Completeness for First-order Properties on Sparse Structures with Algorithmic Applications

RYAN WILLIAMS, MIT

Properties definable in first-order logic are algorithmically interesting for both theoretical and pragmatic reasons. Many of the most studied algorithmic problems, such as Hitting Set and Orthogonal Vectors, are first-order, and the first-order properties naturally arise as relational database queries. A relatively straightforward algorithm for evaluating a property with $k + 1$ quantifiers takes time $O(m^k)$ and, assuming the Strong Exponential Time Hypothesis (SETH), some such properties require $O(m^{k-\epsilon})$ time for any $\epsilon > 0$. (Here, m represents the size of the input structure, i.e., the number of tuples in all relations.)

We give algorithms for every first-order property that improves this upper bound to $m^k/2^{\Theta(\sqrt{\log n})}$, i.e., an improvement by a factor more than any poly-log, but less than the polynomial required to refute SETH. Moreover, we show that further improvement is *equivalent* to improving algorithms for sparse instances of the well-studied Orthogonal Vectors problem. Surprisingly, both results are obtained by showing completeness of the Sparse Orthogonal Vectors problem for the class of first-order properties under fine-grained reductions. To obtain improved algorithms, we apply the fast Orthogonal Vectors algorithm of References [3, 16].

While fine-grained reductions (reductions that closely preserve the conjectured complexities of problems) have been used to relate the hardness of disparate specific problems both within P and beyond, this is the first such completeness result for a standard complexity class.

1 INTRODUCTION

Fine-grained complexity aims to make complexity theory more relevant to algorithm design (and vice versa) by giving reductions that better preserve the times required for solving problems, and connecting algorithmic progress with complexity theory. While some of the key ideas can be traced back to parameterized algorithms and complexity [18, 20], studies of the exact complexity of NP-complete problems [22–24, 29], and algorithmic consequences of circuit lower bounds [6, 8, 21, 25, 26, 28, 37], the full power of this approach has emerged only recently. This approach has given us new circuit lower bounds [32, 34], surprising algorithmic improvements using circuit lower bound techniques [3, 15, 16, 31], and many new insights into the relative difficulty of substantially improving known algorithms for a variety of problems both within and beyond polynomial time.

One of the strengths of this approach also makes it seemingly more complicated. Fine-grained reductions often cut across traditional complexity hierarchies; for example, many results use a now-standard reduction from the NP-complete SAT problem down to the first-order definable (a.k.a. uniform AC^0) orthogonal vectors problem. (Counterintuitively, this reduces a very hard problem to a problem in an extremely simple complexity class). However, different complete problems for the same complexity class can have different time complexities, meaning there may not be fine-grained reductions between them (or at least, that such reductions can be highly non-trivial.) Thus far, fine-grained complexity has remained focused on specific problems, rather than organizing problems into classes as in traditional complexity. As the field has grown, many fundamental relationships between problems have been discovered, making the graph of known results a somewhat tangled web of reductions [1, 2, 5, 9, 11–13, 27, 36].

Here, we give the first results in fine-grained complexity that apply to an entire complexity class, namely the class of first-order definable properties (the uniform version of AC^0). This class is both algorithmically natural in that it contains many standard problems considered before (such as Hitting Set and Orthogonal Vectors), and motivated by its importance in logic and database theory. It is not difficult to see that checking whether a property expressible by a first-order formula with $k + 1$ quantifiers holds on a given structure with m records can be done in $O(m^k)$ time, and if Strong Exponential Time Hypothesis (SETH) is true, there are such properties that require $m^{k-o(1)}$ time to decide.¹ For $k = 1$, this is linear time and so cannot be improved. For each such problem with $k \geq 2$, we give an algorithm that solves it in $m^k / 2^{\Theta(\sqrt{\log m})}$ time. (This improves the standard algorithm by a factor more than any poly-log, but less than the polynomial improvement needed to refute SETH.) Moreover, we show that any further improvement is *equivalent* to a similar algorithmic improvement for the well-studied Orthogonal Vectors problem. Surprisingly, both results are obtained by showing that (a version of) the Orthogonal Vectors problem is *complete* under fine-grained reductions for the class of all first-order properties. This is the first completeness result for a previously studied complexity class under fine-grained reducibility. To obtain the algorithmic results, we then apply the counter-intuitive algorithm for the Orthogonal Vectors problem of [3, 16], which uses techniques from circuit lower bounds.

In addition to introducing new algorithms and giving completeness results, our results clarify and simplify our understanding of “complexity within P.” For many of the known SETH-hard problems of interest such as Edit Distance [9], Longest Common Subsequence [1, 5, 13], Dynamic Time Warping [1, 13], Fréchet Distance [12], Succinct Stable Matching [27], and so on, the reduction from SAT passes through the Orthogonal Vectors problem. Thus, if any of these SETH-hard problems

¹Informally, SETH is a hypothesis that CNF SAT cannot be solved substantially faster than 2^n time; see the Preliminaries for a formal statement.

Fig. 1. A diagram of reductions. We simplify this picture and make the reductions to Edit Distance, LCS, and so on, more meaningful.

had substantially improved algorithms, all first-order properties would have similarly improved algorithms. Thus FOPC, the hypothesis that *some* first-order property does not have a substantially faster algorithm, is a useful intermediary between SETH and many of its consequences. FOPC is both equivalent to conjectures concerning many of the previously studied problems [11], and potentially more plausible to SETH-skeptics since it concerns an entire complexity class, while having most of the consequences of SETH. This is summarized in Figure 1. (See Section 2.3 for definitions of problems.)

While we concentrate on the general picture of complexity classes, even special cases of our results for specific problems are of interest. There were no similarly improved algorithms for Orthogonal Vectors with small total Hamming weight (Sparse OV) or related problems such as Sperner Family and 2-Set Cover (in the sparse high-dimensional case), and it was not previously known that the sparse versions of these problems were equivalent.

In addition to having a natural and useful complete problem, the class of first-order properties is important in itself. This class includes many problems studied in the fine-grained complexity literature such as Hitting Set, Orthogonal Vectors, Sperner Family, Diameter 2, Radius 2, k -Independent Set, k -Dominating Set, and so on. First-order properties are also extensively studied in complexity, logic (especially finite model theory and theory of databases) and combinatorics. Algorithms for model-checking first-order properties are inherent in databases (the core of the relational database language *SQL* is equivalent to first-order properties). Roughly speaking, first-order properties are essentially the uniform version of AC^0 in the complexity literature [10].

Since fine-grained complexity is concerned with exact time complexities (distinguishing, e.g., $n^{1.9}$ time from n^2 time), the problem representation is significant. For graph problems, there are two standard representations: adjacency lists (which are good for *sparse* graphs), in which running time is analyzed with respect to the number of edges m , and adjacency matrices (good for *dense* graphs), in which the runtime is a function of the number of vertices, n . For several reasons, we use the sparse adjacency list (list of tuples) representation. First, many of the problems considered such as Orthogonal Vectors are hard already on sparse instances. Second, the complexity of first-order problems in the dense model is somewhat unclear, at least for numbers of quantifiers between 3 and 7 [33]. Third, the sparse model is more relevant for first-order model checking, as databases are represented as lists of records.

1.1 First-order Properties

The problem of deciding whether a structure satisfies a logical formula is called the model checking problem. In relational databases, first-order model checking plays an important role, as first-order queries capture the expressibility of relational algebra. In contrast to the *combined complexity*, where the database and query are both given as input, the *data complexity* measures the running time when the query is fixed. The combined complexity of first-order queries is PSPACE-complete, but the data complexity is in LOGSPACE [30]. Moreover, these problems are also major topics in parameterized complexity theory. In Reference [19], Flum and Grohe organize parameterized first-order model-checking problems (many of which are graph problems) into hierarchical classes based on their quantifier structures. Here, we study model checking from the fine-grained complexity perspective.

More specifically, let φ be a fixed first-order sentence containing free predicates of arbitrary constant arity (and no other free variables). For example, the k -Orthogonal Vectors (k -OV) problem can be expressed by a $(k + 1)$ -quantifier formula $\varphi = (\exists v_1 \in A_1) \dots (\exists v_k \in A_k)(\forall i)[\bigvee_{j=1}^k \neg(v_j[i] = 1)]$. The model-checking problem for φ , denoted MC_φ , is deciding whether φ is true on a given input structure interpreting predicates in φ (e.g., given k sets of vectors, decide k -OV). We sometimes refer to structures as “hypergraphs” (“graphs” when all relations are unary or binary), and relations as edges or hyperedges. We use n to denote size of the universe of the structure and m the total number of tuples in all its relations (size of the structure). Many graph properties such as k -clique have natural first-order representations, and set problems such as Hitting Set are representable in first-order logic using a relation $R(u, S) \equiv (u \in S)$.

We use notation $MC(\Phi)$ for a class of model-checking problems for $\varphi \in \Phi$, with the main focus on classes of $(k + 1)$ -quantifier φ with $k \geq 1$ (denoted $MC(k + 1)$) and restrictions of this class to specific quantifier prefixes (e.g., $MC(\exists\exists\forall)$ for 3-quantifier φ with quantifier prefix $\exists\exists\forall$ when written in prenex normal form). For formal definitions and more examples see Sections 2.2 and 2.3.

We propose the following conjecture on the hardness of model checking of first-order properties.

First-order property conjecture (FOPC): There is an integer $k \geq 2$, so that there is a $(k + 1)$ -quantifier first-order property that cannot be decided in $O(m^{k-\epsilon})$ time, for any $\epsilon > 0$.

1.2 Orthogonal Vectors

In the *Orthogonal Vectors (OV) problem*, we are given a set A of n Boolean vectors of dimension d , and must decide if there are $u, v \in A$ such that u and v are orthogonal, i.e., $u[i] \cdot v[i] = 0$ for all indices $i \in \{1, \dots, d\}$. Another (equivalent) version is to decide with two sets A and B of Boolean vectors whether there are $u \in A$ and $v \in B$ so that u and v are orthogonal. A naïve algorithm for OV runs in time $O(n^2 d)$, and the best known algorithm runs in $n^{2-\Omega(1/\log(d/\log n))}$ [3, 16].

In this article, we introduce a version of OV we call the *Sparse Orthogonal Vectors (Sparse OV) problem*, where the input is a list of m vector-index pairs (v, i) for each $v[i] = 1$ (corresponding to the adjacency list representation of graphs) and complexity is measured in terms of m ; we usually consider $m = O(n^{1+\gamma})$ for some $0 \leq \gamma < 1$. The popular hardness conjectures on OV restrict the dimension d to be between $\omega(\log n)$ (low dimension) and $n^{o(1)}$ (moderate dimension); however in Sparse OV we do not restrict d .

We thus identify three versions of Orthogonal Vector Conjecture, based on the size of the dimension d . In all three conjectures the complexity is measured in the word RAM model with $O(\log n)$ bit words.

Low-dimension OVC (LDOVC): For all $\epsilon > 0$, there is no $O(n^{2-\epsilon})$ time algorithm for OV with dimension $d = \omega(\log n)$.

Moderate-dimension OVC (MDOVC): For all $\epsilon > 0$, there is no $O(n^{2-\epsilon} \text{poly}(d))$ time algorithm that solves OV with dimension d .

Sparse OVC (SOVC): For all $\epsilon > 0$, there is no $O(m^{2-\epsilon})$ time algorithm for Sparse OV, where m is the total Hamming weight of input vectors.

It is known that SETH implies LDOVC [31]. Because MDOVC is a weakening of LDOVC, it follows from the latter.² Like LDOVC, MDOVC also implies the hardness of problems including Edit Distance, LCS, and so on. Here we further show that MDOVC and SOVC are equivalent (see Lemma 1.1).

OV can be extended to the k -OV problem for any integer $k \geq 2$: given k sets $A_1, \dots, A_k$ of Boolean vectors, determine if there are k different vectors $v_1 \in A_1, \dots, v_k \in A_k$ so that for all indices i , $\prod_{j=1}^k v_j[i] = 0$ (that is, their inner product is 0). We naturally define a sparse version of k -OV similar to Sparse OV, where all ones in the vectors are given in a list.

1.3 Main Results

Completeness. First, we show that conjectures for OV defined on dense (moderate-dimension) and sparse models are equivalent under fine-grained reductions, which means MDOVC is true iff SOVC is true (see Lemma 6.2). This also holds for k -OV.

LEMMA 1.1. *For any integer $k \geq 2$, there exist $\delta, \epsilon > 0$ and a $O(n^{k-\epsilon})$ time algorithm solving k -OV with dimension $d = n^\delta$, if and only if there is an $\epsilon' > 0$ and a $O(m^{k-\epsilon'})$ time algorithm for Sparse k -OV, where m is the total Hamming weight of all input vectors.*

Our main result establishes an equivalence of MDOVC and FOPC, showing the completeness of Sparse OV and hardness of (dense) OV for the class of first-order property problems.

THEOREM 1.2. *MDOVC, SOVC, and FOPC are equivalent.*

This article also proves a hardness and completeness result for k -OV, connecting one combinatorial problem to a large and natural class of logical problems. The following theorem states that Sparse k -OV is complete for $MC(\exists^k \forall)$ (and its negation form $MC(\forall^k \exists)$), and hard for $MC(\forall \exists^{k-1} \forall)$ (and its negation form $MC(\exists \forall^{k-1} \exists)$) under fine-grained reductions.

THEOREM 1.3. *If Sparse k -OV with total Hamming weight m can be solved in time $O(m^{k-\epsilon})$ for some $\epsilon > 0$, then all problems in $MC(\exists^k \forall)$, $MC(\forall^k \exists)$, $MC(\forall \exists^{k-1} \forall)$, and $MC(\exists \forall^{k-1} \exists)$ are solvable in time $O(m^{k-\epsilon'})$ for some $\epsilon' > 0$.*

$MC(\exists^k \forall)$ and $MC(\forall^k \exists)$ are interesting sub-classes of $MC(k+1)$: if Nondeterministic SETH is true, then all SETH-hard problems in $MC(k+1)$ are contained in $MC(\exists^k \forall)$ or $MC(\forall^k \exists)$ ([14]).

We will also show that the 2-Set Cover problem and the Sperner Family problem, both in $MC(\exists \forall)$, are equivalent to Sparse OV under fine-grained reductions and thus complete for first-order properties under fine-grained reductions.

Algorithmic results. Combining our reductions with the surprisingly fast algorithm for Orthogonal Vectors by References [3, 16], we obtain improved algorithms for every problem representable as a $(k+1)$ -quantifier first-order property.

THEOREM 1.4. *There is an algorithm solving $MC(k+1)$ in time $m^k / 2^{\Theta(\sqrt{\log m})}$.*

Let us consider the above results in context with prior work on the fine-grained complexity of first-order properties. In Reference [33], Ryan Williams studied the fine-grained complexity of

²Although dimension d is not restricted, we call it “moderate dimension” because such an algorithm only improves on the naive algorithm if $d = n^{O(\epsilon)}$.

dense instances of first-order graph properties. He gave an $n^{k+o(1)}$ -time algorithm for $MC(k+1)$ on *graphs* when k is a sufficiently large constant, and showed that $MC(k+1)$ requires at least $n^{k-o(1)}$ time under SETH. His algorithms only apply to graphs (they look difficult to generalize to even ternary relations), and it seems difficult to point to a specific simple complete problem in this setting. To compare, our results show that the *sparse* case of $MC(k+1)$ (for *all* c -ary relations, for all constants c) is captured by very simple problems (e.g., sparse Orthogonal Vectors), which also leads to an algorithmic improvement for all c -ary relations.

1.4 Organization of This Paper

Section 1 introduced the motivation, some definitions and statements of the main results. In Section 2, we give the formal definitions of the reductions we use, as well as detailed definitions of first-order properties, with first-order representations of common problems in fine-grained complexity. We present a general outline of the proofs in Section 3, and a high-level explanation of key techniques in Section 4.

The full proof starts with the reduction from $MC(\exists^k \forall)$ to k -OV (Section 5), with randomized universe-shrinking self-reduction described in Section 5.1, which is then derandomized in Section 6. Section 8 presents the reduction from $MC(\forall \exists^{k-1} \forall)$ to k -OV, and Section 10 discusses the $m^k / 2^{\Theta(\sqrt{\log m})}$ time algorithm for Sparse OV and, therefore, $MC(k+1)$. We conclude with open problems in Section 11.

2 PRELIMINARIES

2.1 Reductions

To establish the relationship between complexities of different problems, we use the notion of *fine-grained reductions* as defined in Reference [36]. These reductions establish conditional hardness results of the form “If one problem has substantially faster algorithms, then so does another problem.” We will also use *exact complexity reductions* (see definition 2.2), which strengthen the above claim to “if one problem has algorithms improved by a factor $s(m)$, then another problem can be improved by a factor $s^c(m)$ ” for some constant c . (Note that some fine-grained reductions already have this property.) The underlying computational model is the Word RAM with $O(\log n)$ bit words.

Definition 2.1 (Fine-grained reduction ($\leq_{FGR}$)).³ Assume that L_1 and L_2 are languages and T_1 and T_2 are their conjectured running time lower bounds, respectively, where constant factors may be omitted. Then we say $(L_1, T_1) \leq_{FGR} (L_2, T_2)$ if for every $\epsilon > 0$, there exists $\epsilon' > 0$, and an algorithm A_{L_1} for L_1 that runs in time $T_1(n)^{1-\epsilon'}$ on inputs of length n , making q calls to an oracle for L_2 with query lengths $n_1, \dots, n_q$, where $\sum_{i=1}^q (T_2(n_i))^{1-\epsilon} \leq (T_1(n))^{1-\epsilon'}$.

Thus, if L_2 has an algorithm substantially faster than T_2 , L_1 can be solved substantially faster than T_1 .⁴

³To be more precise, this is the fine-grained Turing reduction. For the mapping reductions that preserve fine-grained complexity, we refer to them as fine-grained mapping reductions.

⁴In almost all fine-grained reductions, $T_1 \geq T_2$, that is, we usually reduce from harder problems to easier problems, which may seem counter-intuitive. A harder problem L_1 can be reduced to an easier problem L_2 with $T_1 > T_2$ in two ways: by making multiple calls to an algorithm solving L_2 and/or by blowing up the size of the L_2 instance (e.g., the reduction from CNF-SAT to OV [31]). All reductions from higher complexity to lower complexity problems in this article belong to the first type.

Actually, it is harder to fine-grained reduce from a problem with lower time complexity to a problem with higher time complexity (e.g., prove that $(MC(k), m^{k-1}) \leq_{FGR} (MC(k+1), m^k)$), because this direction often needs creating instances with size much smaller than the original instance size.

To simplify transferring algorithmic results, we define a stricter variant of fine-grained reductions, which we call *exact reductions*. These reductions satisfy a stronger reducibility notion.

Definition 2.2 (Exact complexity reduction ($\leq_{EC}$)). Let L_1 and L_2 be languages and let T_1, T_2 denote time bounds. Then $(L_1, T_1) \leq_{EC} (L_2, T_2)$ if there exists an algorithm A_{L_1} for L_1 running in time $T_1(n)$ on inputs of length n , making calls to oracle of L_2 with query lengths $n_1, \dots, n_q$, where q is the number of calls and $\sum_{i=1}^q T_2(n_i) \leq T_1(n)$.

That is, if L_2 is solvable in time $T_2(n)$, then A_{L_1} solves L_1 in time $T_1(n)$.

2.2 Model Checking for First-order Logic

Let $R_1, \dots, R_r$ be predicates of constant arities $a_1, \dots, a_r$ (a vocabulary). A finite *structure* over the vocabulary $R_1, \dots, R_r$ consists of a *universe* U of size n together with r lists, one for every R_i , of m_i tuples of elements from U on which R_i holds. Let $m = \sum_{i=1}^r m_i$; viewing the structure as a database, m is the total number of records in all tables (relations).

We loosely use the term *hypergraph* to denote an arbitrary structure; in this case, we refer to its universe as a set of vertices $V = \{v_1, \dots, v_n\}$ and call tuples $(v_1, \dots, v_{a_i})$ such that $R_i(v_1, \dots, v_{a_i})$ holds hyperedges (labeled R_i). A set of all R_i -labeled hyperedges in a given hypergraph is denoted by E_{R_i} or just E_i ; the structure is denoted by $G = (V, E_1, \dots, E_r)$. Similarly, we use the term *graph* for structures with only unary and binary relations (edges); here, we mean edge-labeled vertex-labeled directed graphs with possible self-loops, as we allow multiple binary and unary relations and relations do not have to be symmetric. This allows us to use graph terminology such as a *degree* (the number of (hyper)edges containing a given vertex) or a neighbourhood of a vertex.

Let φ be a first-order sentence (i.e., formula without free first-order variables) containing predicates $R_1, \dots, R_r$. Let k be the number of quantifiers in φ . Without changing k , we can write φ in prenex form. The *model-checking problem* for a *first-order property* φ , MC_φ , is: given a structure (hypergraph) G , determine whether φ holds on G (denoted by $G \models \varphi$). For a class of formulas Φ , we use the notation $MC(\Phi)$ for a class of model-checking problems for $\varphi \in \Phi$, with shortcuts $MC(k)$ for $\Phi = k$ -quantifier first-order formulas in prenex form, and $MC(Q_1 \dots Q_k)$ for first-order prenex formulas with quantifier prefix $Q_1 \dots Q_k$, with a shortcut Q_i^c denoting c consecutive occurrences of Q (e.g., $MC(\exists^k \forall)$).

We assume that (hyper)graphs are given as a list of m (hyper)edges, with each hyperedge encoded by listing its elements. In the Word RAM model with $O(\log n)$ bit words, the size of an encoding of a hypergraph is $O(n + m)$ words, and an algorithm can access a hyperedge in constant time. With additional $O(m)$ time preprocessing, we can compute degrees and lists of incident edges for each vertex, and store them in a hash table for a constant-time look-up; edges incident to a vertex can then be listed in time proportional to its degree. We also assume that $m \geq n$, with every vertex incident to some edge, because the interesting instances are in this case. Moreover, we assume the (hyper)graph is k -partite, where k is the number of variables in φ , so that each variable is selected from a distinct vertex set. From any (hyper)graph, the construction of this k -partite graph needs a linear time, linear space blowup preprocessing that creates at most k duplicates of the vertices and k^2 duplicates of the edges. Finally, we treat domains of quantifiers as disjoint sets forming a partition of the universe; any structure can be converted into this form with constant increase of the universe size. We also view predicates on different variable sets (e.g., $R(x_1, x_2)$ vs. $R(x_2, x_4)$ vs. $R(x_4, x_4)$) as different predicates, and partition corresponding edge sets appropriately.

The focus of this article is on *sparse* structures, that is, the case when $m \leq O(n^{1+\gamma})$ for some γ such that $0 \leq \gamma < 1$. In particular, all E_i are sparse relations; we use the term *co-sparse* to refer to complements of sparse relations. We will usually measure complexity as a function of m . From the

following baseline algorithm that will be proved in Section 9.1, the sparse assumption is without loss of generality.

CLAIM 2.1 (BASELINE ALGORITHM). $MC(k+1)$ is solvable in time $O(n^{k-1}m)$.

2.3 Common Problems and Conjectures

In the CNF-SAT problem, given a Boolean formula F in CNF form (conjunction of disjunctions of (possibly negated) variables), the goal is to determine whether there is an assignment of Boolean values to variables of F that makes F true. In k -CNF-SAT, every clause (disjunction) can have at most k literals. We refer to the following conjecture about complexity of solving CNF-SAT:

Strong Exponential Time Hypothesis (SETH)⁵: For every $\epsilon > 0$, there exists a $k \geq 2$ so that k -CNF-SAT cannot be solved in time $O(2^{n(1-\epsilon)})$.

Below we list some problems studied in fine-grained complexity, with their first-order definitions on structures with unary and binary relations.

- **Graph problems.** The input structure is $G = (V, E)$ with a universe V and a binary relation E .
 1. *Diameter-2*: $(\forall x_1)(\forall x_2)(\exists x_3)[E(x_1, x_3) \wedge E(x_3, x_2)]$.
 2. *Radius-2*: $(\exists x_1)(\forall x_2)(\exists x_3)[E(x_1, x_3) \wedge E(x_3, x_2)]$.
 3. *k-Clique*: $(\exists x_1) \dots (\exists x_k)[\bigwedge_{i,j \in \{1, \dots, k\}, i \neq j} E(x_i, x_j)]$. More generally, for a fixed graph H of k vertices, deciding if H is a subgraph or induced subgraph of the input graph G (e.g., the k -Independent Set problem) can be expressed in a similar way.
 4. *k-Dominating Set*: $(\exists x_1) \dots (\exists x_k)(\forall x_{k+1})[\bigvee_{i=1}^k E(x_i, x_{k+1})]$.
- **Set problems.** The inputs are set families $\mathcal{S}$ or $\mathcal{S}_1, \dots, \mathcal{S}_k$ over a universe U . Here, all sets are given explicitly and represented by first-order variables. These structures contain a single binary predicate $\in$.
 1. *Hitting Set*:⁶ $(\exists H \in \mathcal{S})(\forall S \in \mathcal{S})(\exists x)[(x \in H) \wedge (x \in S)]$.
 2. *k-Set Packing*: $(\exists \mathcal{S}_1 \in \mathcal{S}) \dots (\exists \mathcal{S}_k \in \mathcal{S})(\forall x)[\bigvee_{i=1}^k ((x \in \mathcal{S}_i) \rightarrow \bigwedge_{j \neq i} (x \notin \mathcal{S}_j))]$.
 3. *k-Empty Intersection (k-OV)*: $(\exists \mathcal{S}_1 \in \mathcal{S}_1) \dots (\exists \mathcal{S}_k \in \mathcal{S}_k)(\forall u \in U)[\bigvee_{i=1}^k \neg(u \in \mathcal{S}_i)]$.
 4. *k-Set Cover*: $(\exists \mathcal{S}_1 \in \mathcal{S}_1) \dots (\exists \mathcal{S}_k \in \mathcal{S}_k)(\forall u \in U)[\bigvee_{i=1}^k (u \in \mathcal{S}_i)]$.
 5. *Set Containment*: $(\exists \mathcal{S}_1 \in \mathcal{S}_1)(\exists \mathcal{S}_2 \in \mathcal{S}_2)(\forall u \in U)[(\neg(u \in \mathcal{S}_1)) \vee (u \in \mathcal{S}_2)]$.

k -Empty Intersection is equivalent to k -OV, and Set Containment is equivalent to Sperner Family problem. See Section 1.2 for definitions and conjectures for variants of the Orthogonal Vectors problem.

The **Hitting Set Conjecture** states that $\forall \epsilon > 0$ there is no $O(n^{2-\epsilon})$ time algorithm for the Hitting Set problem with set sizes bounded by $d = \omega(\log n)$. It implies LDOVC; subquadratic approximation algorithms for Diameter-2 and Radius-2 would, respectively, refute the LDOVC and the Hitting Set Conjecture [4].

3 OVERVIEW

The main technical part of this article is in the proof of Theorem 1.3 showing hardness of k -OV for model-checking of $\exists^k \forall$ formulas under fine-grained reductions. The idea is to represent $\exists^k \forall$ formulas using combinations of basic “ k -OV like” problems, each of which is either easy (solvable substantially faster than m^k time for sparse instances) or can be fine-grained reduced to k -OV. The

⁵Some define SETH over randomized algorithms instead of deterministic ones.

⁶Other versions of Hitting Set, where the sets are not given explicitly are second-order logic problems. Our definition here is consistent with the version in the Hitting Set Conjecture.

Fig. 2. Overview of the reduction process for Theorem 1.2.

latter is achieved using a universe-shrinking self-reduction, which converts a given instance of a basic problem to a denser instance on a smaller universe, thus reducing Sparse k -OV to k -OV with dimension n^δ and proving Lemma 1.1. Converting an $MC(\exists^k \forall)$ to the “hybrid problem” combining all 2^k basic problems is done for graphs (all relations have arity at most 2); however, we show that this is the hardest case. Additionally, $MC(\forall \exists^{k-1} \forall)$ is reduced to $MC(\exists^k \forall)$.

In Theorem 1.2 and Theorem 1.4, we consider the class of all $k + 1$ -quantifier first-order properties $MC(k + 1)$, and reduce it to 2-OV, proceeding to use a faster algorithm for 2-OV to speed up model checking. The first step is to brute-force over first $k - 2$ quantified variables, reducing to three-quantifier case at the cost $O(n^{k-2})$. The quantifier prefix $\exists \exists \forall$, with 2-OV and other basic problems (to be defined in Section 5.1), is the hardest ($\exists^3$, $\forall \exists \exists$ and their complements are easy, and the rest reduce to $\exists \exists \forall$). Appealing to lemmas in the proof of Theorem 1.3 with $k = 2$ completes the proof of Theorem 1.2 (see Figure 2 for details), and applying the OV algorithm in References [3, 16] gives Theorem 1.4.

3.1 Reduction from $MC(k + 1)$ to OV

The following outlines the reduction from any arbitrary problem in $MC(k + 1)$ to OV for any integer $k \geq 2$, thus proving that FOPC implies SOVC. For the other direction of this equivalence, SOVC implies FOPC because Sparse OV is in $MC(3)$. The equivalence between SOVC and MDOVC is proven in Lemma 1.1, which in turn follows from Lemma 5.2, Lemma 6.2, and corollary 5.3.

- (1) With brute-force over tuples of first $k - 2$ variables, we reduce from the $(k + 1)$ -quantifier problem MC_φ down to a 3-quantifier problem $MC_{\varphi'}$. Thus, improving the $O(m^2)$ algorithm for $MC_{\varphi'}$ implies improving the $O(m^k)$ algorithm for MC_φ .
- (2) If $MC_{\varphi'}$ belongs to one of $MC(\exists \exists \exists)$, $MC(\forall \forall \forall)$, $MC(\forall \exists \exists)$, $MC(\exists \forall \forall)$, then we solve it directly in time $O(m^{3/2})$, using ideas similar to triangle detection algorithms. If φ' has the quantifier structure $\forall \exists \forall$ (or its negated form $\exists \forall \exists$), then we reduce $MC_{\varphi'}$ to $MC_{\varphi''}$, where φ'' has quantifier structure $\exists \exists \forall$, using Lemma 8.1. Otherwise, φ' is already in $\exists \exists \forall$ or equivalent form.
- (3) We reduce a general model checking problem for φ'' of the quantifier structure $\exists \exists \forall$ to a graph property problem of the same quantifier structure.
- (4) Using Lemma 5.6, we reduce formulas of form $\exists \exists \forall$ to a “hybrid” problem, which by Lemma 5.5 can be reduced to a combination of Sparse OV, Set Containment and 2-Set Cover (which we call *Basic Problems*).

- (5) We use a “universe-shrinking” technique (Lemmas 5.2, 6.1, and 6.2) on each of the Basic Problems, to transform a sparse instance into an equivalent one of small dimension.
- (6) After applying this to the Hybrid Problem, we can complement edge relations as needed to transform all Basic Problems into OV (Lemmas 5.4 and 6.3).
- (7) By applying the References [3, 16] algorithm to the instance of low-dimension OV, we get an improved algorithm.

Figure 2 shows a diagram of the above reduction process.

Moreover, Lemmas 8.1, 5.6, 5.5, and 5.1 also work for any constant $k \geq 2$. So for a problem in $MC(\exists^k \forall)$ or $MC(\forall \exists^{k-1} \forall)$, we can reduce it to k -OV as follows:

- (1) If the problem belongs to $MC(\forall \exists^{k-1} \forall)$, then reduce it to $MC(\exists^k \forall)$ using Lemma 8.1.
- (2) Eliminate hyperedges, then reduce the $MC(\exists^k \forall)$ to the Hybrid problem using Lemma 5.6.
- (3) Reduce from the Hybrid Problem to a combination of 2^k Basic Problems, using Lemma 5.5.
- (4) Reduce all Basic Problems to k -OV, using Lemma 5.1.

This completes the proof of Theorem 1.3.

4 THE BUILDING BLOCKS

Before the formal presentation of the reduction algorithms, this section gives an intuitive and high-level view of the techniques used to reduce a first-order property problem to OV, in the proofs of Theorems 1.2, 1.3, and 1.4. Because of Lemma 1.1, in the remainder of this article, unless specified, we will use “OV” and “ k -OV” to refer to sparse versions of these problems.

4.1 Complementing Sparse Relations

Recall the definitions of the k -Empty Intersection, k -Set Cover and Set Containment problems⁷ from Section 2.3. These problems have very similar structure: given set families $S_1 \dots S_k$ containing sets over elements of the universe U , each of them asks whether there is a tuple of sets, one in each family, such that a formula is satisfied for every element u of the universe. Moreover, the formulas themselves are disjunctions of $u \in S_i$ or $u \notin S_i$, with one predicate for each i . The only difference is the polarity of the $\in$ relation (whether or not it is negated). We will refer to these types of problems as the *Basic Problems*; they will be our main building blocks.

For $k = 2$, this gives us four basic problems: Set Disjointness, 2-Set Cover and two versions of Set Containment (direct and reversed). In each of them, the input consists of two set families S_1, S_2 of sizes n_1, n_2 , respectively, and the universe U of size n_u . The goal is to decide if there exist sets $S_1 \in \mathcal{S}_1$ and $S_2 \in \mathcal{S}_2$ such that for every $u \in U$, the corresponding formula ψ_ℓ holds. Here, $\ell \in \{00, 01, 10, 11\}$ codes the sequence of polarities of occurrences of $\in$. This naturally generalizes to arbitrary k , with a Basic Problem for each $\ell \in \{0, 1\}^k$; see Section 5.1 for formal definitions.

That is, Set Disjointness, 2-Set Cover and Set Containment can be stated as follows. Decide if $\exists S_1 \in \mathcal{S}_1 \exists S_2 \in \mathcal{S}_2 \forall u \in U \psi_\ell$ holds, where ψ_ℓ is as follows:

Set Disjointness: There is no common element in S_1 and S_2 : $\psi_\ell = \psi_{00} = \neg(u \in S_1) \vee \neg(u \in S_2)$.

2-Set Cover: Union of S_1 and S_2 covers all of U : $\psi_\ell = \psi_{11} = (u \in S_1) \vee (u \in S_2)$.

⁷OV is also 2-EI or Set Disjointness: k -EI is equivalent to k -OV, where vectors are represented by sets containing their 1s. Set Containment is equivalent to the Sperner Family, and k -Set Cover to k -Dominating Set under linear-time reductions.

Set Containment: For $S_1 \subseteq S_2$, $\psi_\ell = \psi_{01} = \neg(u \in S_1) \vee (u \in S_2)$. Similarly, in reversed Set Containment with $S_2 \subseteq S_1$, $\psi_\ell = \psi_{10} = (u \in S_1) \vee \neg(u \in S_2)$.

All these problems are first-order properties: We can use unary relations to partition the vertex set into $(S_1, \dots, S_k, U)$, and consider the relation “ $\in$ ” as a binary relation. We will use the context of hypergraphs to describe the input structure, as in Section 2.2. We let n (corresponding to the number of vertices in the input graph) be the sum of $n_1, \dots, n_k$ and n_u , and let the input size m (corresponding to the number of edges in the input graph) be the sum of all sets’ sizes in all set families. Borassi et al. [11] showed that when $k = 2$, these Basic Problems require time $m^{2-o(1)}$ under SETH, and that if the size of universe U is poly-logarithmic in the input size, then the three problems are equivalent under subquadratic-time reductions. The main idea of the reductions between these problems is to complement all sets in S_1 , or S_2 , or both. It is easy to see that $S_1 \cap S_2 = \emptyset \iff S_1^c \cup S_2^c = U \iff S_1 \subseteq S_2^c \iff S_2 \subseteq S_1^c$. Therefore, if we could complement the sets, we can easily prove the equivalences between the three Basic Problems. However, we cannot do this when n_u is large.

For a sparse binary relation such as $(u \in S_1)$, we say that its complement, such as $(u \notin S_1)$, is *co-sparse*. Suppose we want to enumerate all tuples (S_1, u) s.t. $u \in S_1$; for that, we can go through all relations (aka edges) between U and S_1 , which takes time linear in m . On the contrary, if we want to enumerate all pairs (S_1, u) s.t. $u \notin S_1$, we cannot do this in linear time, because we cannot touch the pairs by touching edges between them. Moreover, when n_u is as large as $\Omega(n)$, the number of such pairs can reach $\Theta(m^2)$. When $k = 2$, a fine-grained reduction between $O(m^2)$ -time problems allows neither quadratic time reductions, nor quadratic size problem instances.

Because of the above argument, it is hard to directly reduce between the Basic Problems, so instead we reduce each problem to a highly asymmetric instance of the same problem, where sparse relations are easily complemented to relations that are also sparse. Observe that when the size of universe U is small enough, complementing all sets can be done in time $O(m \cdot |U|)$, which can be substantially faster than $O(m^2)$. The new instance created also has size $O(m \cdot |U|)$, so that it is only slightly larger than m . So by carefully choosing the size of U , we can construct truly subquadratic time reduction algorithms that preserve the improved factor in running time. Using this technique that we call *universe-shrinking self-reduction*, we can show that OV, 2-Set Cover and Set Containment are equivalent under fine-grained reductions.

The self-reduction employs the “high-degree low-degree” trick, which has been also used in other sparse graph algorithms [7]. First, consider sets of large cardinality: there cannot be too many of them, because the structure is sparse. Thus, we can do exhaustive search over these sets to check if any of them is in a solution. For sets of small cardinality, we hash the universe U to a smaller universe, where complementing the sets does not take too much time and space. From this reduction, the claim follows:

CLAIM 4.1. *If any one of OV, 2-Set Cover and Set Containment has truly subquadratic time algorithms, then the other two are also solvable in subquadratic time. Thus these problems are all hard for MC(3).*

Claim 4.1 is itself an interesting result: In Reference [11], conditional lower bounds for many problems stem from the above three problems, forming a tree of reductions. By our equivalence, the root of the tree can be replaced by the quadratic-time hardness conjecture on any of the three problems, simplifying the reduction tree. Claim 4.1 also shows that an improved algorithm for any of these three problems implies improved algorithms for the other two.

Claim 4.1 is proven by derandomizing Lemma 5.1 for $k = 2$; see Section 6 for details. In Section 5, we give randomized reductions for an arbitrary k .

4.2 Sparse and Co-sparse Relations

Having shown how to reduce any two Basic Problems with the same k to each other, we will now reduce generic first-order properties to the Basic Problems. The detailed processes are complicated, so here we start with a high-level idea in reductions and algorithm design throughout the article.

Our algorithms often need to iterate over all tuples or pairs (x_i, x_j) satisfying some conditions, to list such tuples, or to count the number of them, performing first-order *query processing*. A set of such tuples (pairs) (x_i, x_j) can be considered a result of a *first-order query* defined by an intermediate formula φ' on the (hyper)graph G (or some intermediate structures). Our reduction algorithms often generate such queries, evaluate them, and combine the results (e.g., by counting) to compute the solutions.

There are three possible outcomes of such queries: the result can be a sparse set of tuples, a co-sparse set, or neither. If the result of the query is a sparse relation such as $[R_1(x_1, x_2) \wedge \neg R_2(x_1, x_2)]$, then we can iterate over the tuples (say, first enumerate all pairs satisfying $R_1(x_1, x_2)$, then check for which of them $R_2(x_1, x_2)$ is false). Then, we can do further operations on the sparse set of (x_1, x_2) tuples resulting from the query. When the result of the query is a co-sparse set such as for $[\neg R_1(x_1, x_2) \wedge \neg R_2(x_1, x_2)]$, we cannot directly iterate over pairs satisfying the query. Instead, we work on its complement (which is sparse, instead of co-sparse), but then do some further processing to filter out those pairs from future use (say, find all pairs (x_1, x_2) so that at least one of $R_1(x_1, x_2)$ or $R_2(x_1, x_2)$ is true, then exclude those pairs from future use). Sometimes, the result of a query is neither sparse nor co-sparse, but we will show it is always a combination of sparse and co-sparse relations. Thus, we need to distinguish them and deal with the sparse and co-sparse parts separately.

We exemplify this process by considering the query $[\neg R_1(x_1, x_2) \vee \neg R_2(x_1, x_2)]$. For a pair (x_1, x_2) , to make the formula true, predicates R_1, R_2 can be assigned values from $\{(True, False), (False, True), (False, False)\}$. In the first two cases, the sets of pairs (x_1, x_2) satisfying $[R_1(x_1, x_2) \wedge \neg R_2(x_1, x_2)]$ and $[\neg R_1(x_1, x_2) \wedge R_2(x_1, x_2)]$ are sparse, while in the last case, the set of pairs satisfying $[\neg R_1(x_1, x_2) \wedge \neg R_2(x_1, x_2)]$ is co-sparse. So if we want to work on the tuples satisfying this query, we list tuples satisfying the first two cases directly by enumerating edges, and enumerate the tuples *not* satisfying the third case (i.e., the tuples, where either $R_1(x_1, x_2)$ or $R_2(x_1, x_2)$ is true), to exclude them from future use.

In general, a query can be written as a DNF, where the result of each term is a conjunction of predicates and negated predicates, and therefore either sparse or co-sparse. Then we can deal with the sparse and co-sparse cases separately. We will use this technique for constructing the Hybrid Problem in Section 5.2.

Now, we would like to reduce MC_φ to OV for an arbitrary $\varphi = (\exists x)(\exists y)(\forall z)\psi(x, y, z)$. First, suppose that all predicates $R_1 \dots R_r$ in ψ are at most binary, and all binary predicates involve z . One attempt is to create a set S_x for each element x and a set S_y for each element y . Then, we create elements in universe U by creating 2^r elements $u_{(z, 0^r)}, \dots, u_{(z, 1^r)}$ for each z , where r is the number of different predicates in ψ , and the length- r strings in the subscripts correspond to the 2^r truth assignments of all these predicates. We construct the sets so that S_x (or S_y) contains element $u_{(z, a)}$ iff the assignment a falsifies ψ and the relations between x (or y) and z agree with a . In this way, sets S_x and S_y both contain some element $u_{(z, a)}$ in U iff there is some z such that x, y, z do not satisfy ψ . Then, if there exists such pair of disjoint sets S_x and S_y , the corresponding x and y satisfy that for all z , ψ is true.

However, we cannot touch all z 's for each x or y for creating this instance in substantially less than n^2 time. So, we divide the relations of this Set Disjointness instance into sparse and co-sparse

ones. For that, we introduce a *Hybrid Problem* that is a combination of Basic Problems. Depending on the four combinations of sparsity or co-sparsity on the relations between variables x, z and y, z , we reduce MC_φ not only to OV, but to a combination of OV, Set Containment, reversed Set Containment (i.e., finding $S_2 \subseteq S_1$ instead of $S_1 \subseteq S_2$), and 2-Set Cover. (Namely, the sub-problem Set Disjointness deals with the case, where the relations between x and z and between y and z are both sparse; the sub-problems Set Containment, reversed Set Containment and 2-Set Cover deals with the cases, where these relations are sparse and co-sparse, co-sparse and sparse, co-sparse and co-sparse, respectively.) We decide if there is a pair of sets being the solutions of all sub-problems. Finally, because these Basic Problems can be reduced to each other, we can use the algorithm for OV to solve the instance of the Hybrid Problem, and then to solve MC_φ .

This approach takes care of binary predicates involving z ; to handle relations among existentially quantified variables, additional tools are needed. Thus, the Hybrid Problem definition also involves a relation $R(x, y)$ and a “sparsity type” designation, specifying whether R codes a sparse relation between x and y , or its sparse complement. However, this additional information can be modeled by adding new elements to the universe and strategically placing them in the corresponding sets, thus reducing the more complex case to a combination of four Basic Problems.

See Lemma 5.6 for the proof that covers more complicated cases.

5 COMPLETENESS OF k -OV IN $MC(\exists^k \forall)$

This section will prove the completeness of k -OV in $MC(\exists^k \forall)$ problems. Here we only consider the input structures that are graphs, i.e., where all relations are either unary or binary; see Section 7 of this article for the reduction from hypergraphs to graphs. First, we introduce a class of Basic Problems, and prove that these problems are equivalent to k -OV under exact complexity reductions. Then, we show that any problem in $MC(\exists^k \forall)$ can be reduced to a combination of Basic Problems (a.k.a. the Hybrid Problem).

5.1 How to Complement a Sparse Relation: Basic Problems and Reductions between Them

In this section, we define the Basic Problems for $k \geq 2$, generalizing k -OV, k -Set Cover and Set Containment problems, and prove that these problems are fine-grained reducible to each other under randomized reductions. In Section 6, we will give deterministic reductions for $k = 2$.

Let $k \geq 2$. We introduce 2^k Basic Problems labeled by k -bit binary strings from 0^k to 1^k . The input of these problems is the same as that of k -EI defined in Section 2.3: k set families $\mathcal{S}_1 \dots \mathcal{S}_k$ of size $n_1, \dots, n_k$ on a universe U of size n_u . We define 2^k quantifier-free formulas $\psi_{0^k}, \dots, \psi_{1^k}$ such that

$$\psi_\ell = \left(\bigvee_{i, \ell[i]=0} (\neg(u \in S_i)) \right) \vee \left(\bigvee_{i, \ell[i]=1} (u \in S_i) \right).$$

Here, $i \in \{1, \dots, k\}$ and $\ell[i]$, the i th bit of label ℓ , specifies whether u is in each S_i or not in the i th term of ψ_ℓ .

For each ℓ , let $\varphi_\ell = (\exists S_1 \in \mathcal{S}_1) \dots (\exists S_k \in \mathcal{S}_k)(\forall u \in U)\psi_\ell$. For simplicity, we will omit the domains of the variables in these formulas. We call $MC_{\varphi_{0^k}}, \dots, MC_{\varphi_{1^k}}$ the Basic Problems. We refer to the Basic Problem MC_{φ_ℓ} as $BP[\ell]$. These problems are special cases of first-order model checking on graphs, where sets and elements correspond to vertices, and membership relations correspond to edges. Note that $BP[0^k]$ is k -EI, and $BP[1^k]$ is k -Set Cover. When $k = 2$, $BP[01]$ and $BP[10]$ are Set Containment problems, and $BP[00]$ is the Set Disjointness problem. For a k -tuple

($S_1 \in \mathcal{S}_1, \dots, S_k \in \mathcal{S}_k$) satisfying $(\forall u) \psi_\ell$, we call it a *solution* of the corresponding Basic Problem $BP[\ell]$.

We present a randomized⁸ fine-grained mapping reduction between any two Basic Problems, thus proving the following lemma, which generalizes Claim 4.1 to $k > 2$.

LEMMA 5.1. *Let $s(m)$ be a non-decreasing function such that $2^{\Omega(\sqrt{\log m})} \leq s(m) < m^{1/5}$. For any $\ell_1, \ell_2 \in \{0, 1\}^k$, there is a randomized exact complexity reduction $(BP[\ell_1], m^k/(s(m))^{1/6}) \leq_{EC} (BP[\ell_2], m^k/s(m))$.*

For problems $BP[\ell_1]$ and $BP[\ell_2]$, where ℓ_1 and ℓ_2 only differ in the i th bit, if we are allowed to complement all sets in $\mathcal{S}_i$, we can easily reduce between them. Similarly, if ℓ_1 and ℓ_2 differ in more than one bit, we can complement all the sets in corresponding set families. However, complementing the sets in $\mathcal{S}_i$ takes time $O(n_i n_u)$, which might be as large as $\Theta(m^2)$. To solve this, we self-reduce $BP[\ell_1]$ on the universe U to the same problem on a smaller universe U' , and then complement sets on U' . For any given δ , if the size of U' is $n'_u = O(m^\delta)$, then complementing all sets in $\mathcal{S}_i$ only takes time and space $m \cdot O(m^\delta) = O(m^{1+\delta})$.

LEMMA 5.2. *(Randomized universe-shrinking self-reductions of Basic Problems)*

Let label ℓ be any binary string in $\{0, 1\}^k$. For any $s(m) = 2^{\Omega(\sqrt{\log m})}$, given a $BP[\ell]$ instance I of size m and universe U of size n_u , we can either solve it in time $O(m^k/s(m))$, or use time $O(m^k/s(m))$ to create a $BP[\ell]$ instance I' of size $O(m \cdot s(m)^5)$ on universe U' whose size is $n'_u = O(s(m)^5)$, so that $I \in BP[\ell]$ iff $I' \in BP[\ell]$ with error probability bounded by $O(1/s(m))$.

Note that the self-reduction of k -OV actually reduces the Sparse k -OV to a moderate-dimension version of k -OV, implying Lemma 1.1. The other direction (moderate-dimension k -OV to Sparse k -OV) is easy since if the dimension $d = n^\delta$, then m is at most $d \cdot n = n^{1+\delta}$, as required.

COROLLARY 5.3. *(Reverse direction of Lemma 1.1)*

Suppose that for any $k \geq 2$ there exists $\delta, \epsilon > 0$ and a (randomized) $O(n^{k-\epsilon})$ algorithm solving k -OV with dimension $d = n^\delta$. Then there is an $\epsilon' > 0$ and a (randomized) $O(m^{k-\epsilon'})$ time algorithm solving Sparse k -OV.

PROOF. The algorithm converts an instance of Sparse k -OV to an instance of k -OV of dimension n^δ using universe-shrinking self-reduction (Lemma 5.2) and then applies assumed $O(n^{k-\epsilon})$ time algorithm to the reduced instance. More specifically, let $m = O(n^{1+\gamma})$, where n is the number of vectors. Choosing $s(m) = O(m^{\delta/5/(1+\gamma)})$ for some $\delta > 0$ creates an instance of OV with dimension $n'_u = O(s(m)^5) = O(n^\delta)$, and size $m' = O(n^{1+\delta+\gamma})$; number of vectors n remains unchanged. Now, the reduction takes time $O(m^k/(s(m))^5) = O(m^{k-\delta/(1+\gamma)})$, and running the $O(n^{k-\epsilon})$ time algorithm on the reduced instance takes $O(n^{k-\epsilon}) \leq O(m^{k-\epsilon/(1+\gamma)})$ time. Setting $\epsilon' = \min\{\delta/(1+\gamma), \epsilon/(1+\gamma)\}$ completes the proof. $\square$

We will present the randomized self-reductions for problems $BP[\ell]$ s.t. $\ell \neq 1^k$ in Section 5.1.1. For $BP[1^k]$, we will prove that it is either easy to solve or easy to complement in Section 5.1.2.

After shrinking the universe, we complement the sets to reduce between two Basic Problems $BP[\ell_1]$ and $BP[\ell_2]$ according to the following lemma.

LEMMA 5.4 (REDUCTION BETWEEN DIFFERENT BASIC PROBLEMS). *For two different labels $\ell_1, \ell_2 \in \{0, 1\}^k$, given set families $\mathcal{S}_1, \dots, \mathcal{S}_k$, let $\mathcal{S}'_1, \dots, \mathcal{S}'_k$ be defined such that*

⁸The deterministic reduction will be presented in Section 6.

$$S'_i = \begin{cases} \{S_i^G \mid S_i \in \mathcal{S}_i\}, & \text{if } \ell_1[i] \neq \ell_2[i] \\ \mathcal{S}_i, & \text{otherwise} \end{cases},$$

then, $(\exists S_1 \in \mathcal{S}_1) \dots (\exists S_k \in \mathcal{S}_k) (\forall u) \psi_{\ell_1}$ iff $(\exists S'_1 \in \mathcal{S}'_1) \dots (\exists S'_k \in \mathcal{S}'_k) (\forall u) \psi_{\ell_2}$.

The proof of correctness is straightforward.

PROOF OF LEMMA 5.1. Pick $s'(m) = s(m)^{1/(6k)}$. Using Lemma 5.2, we shrink the universe to size $n'_u = s'(m)^5$. So the time complexity in this step is bounded by $O(m \cdot s'(m)^5)$, which is significantly less than $m^k/s(m)$ even if $k = 2$.

Let new instance size be m' . So $m' = m \cdot s'(m)^5$. Given that the constructed instance can be decided in time $m'^k/s(m')$, we get $m'^k/s(m') < (m(s(m)^{1/(6k)})^5)^k/s(m) < m^k/s(m)^{1/6}$. Thus, by the two-step fine-grained mapping reductions given by Lemma 5.2 and Lemma 5.4, we have an exact complexity reduction between any two Basic Problems, completing the proof for Lemma 5.1. $\square$

5.1.1 Randomized Universe-shrinking Self-reduction of $BP[\ell]$ Where $\ell \neq 1^k$. This section proves part of Lemma 5.2, by giving a randomized universe-shrinking self-reduction of $BP[\ell]$, where $\ell \neq 1^k$. The main idea is to divide the sets into large and small ones. For large sets, there are not too many of them in the sparse structure, so we can work on them directly. For small sets, we use a Bloom Filter mapping each element in U to some elements in U' at random, and then for each set on universe U , we compute the corresponding set on universe U' . Next we can decide the same problem on these newly computed sets, instead of sets on U . (Reference [17] used a similar technique in reducing from Orthogonal Range Search to the Subset Query problem.) Because the sets are small, it is unlikely that some elements in two different sets on U are mapped to the same element on U' , bounding the error probability.

- **Step 1: Large sets.** Let $d = s(m)$. For sets of size at least d , we directly check if they are in any solutions. There are at most $O(m/d) = O(m/s(m))$ of such large sets. In the outer loop, we enumerate all large sets in $\mathcal{S}_1, \dots, \mathcal{S}_k$. If their sizes are pre-computed, then we can do the enumeration in $O(m/s(m))$. Assume the current large set is $S_i \in \mathcal{S}_i$. Because variables quantified by $\exists$ are interchangeable, we can interchange the order of variables, and let S_i be the outermost quantified variable S_1 . On each such S_i (or S_1 after interchanging), we create a new formula ψ_{S_1} on variables $S_2, \dots, S_k, u$ from formula ψ , by replacing $u \in S_1$ ($u \notin S_1$) by a unary relation on u . Then, we decide if the graph induced by $S_2, \dots, S_k$ and U satisfies $(\exists S_2) \dots (\exists S_k) (\forall u) \psi_{S_1}$, using the baseline algorithm, which takes time $O(m^{k-1})$ for each such large set S_1 . Thus the overall running time is $O(m/s(m)) \cdot O(m^{k-1}) = O(m^k/s(m))$. If no solution is found in this step, then proceed to Step 2.
- **Step 2: Small sets.** Now we can exclude all the sets of size at least d . For sets of size smaller than d , we do the self-reduction to universe U' of size $n'_u = s(m)^5$. Let $t = s(m)$, and let $h : U \rightarrow U'^t$ be a function that independently maps each element $u \in U$ to t elements in U' at random. On set $S \subseteq U$, we overload the notation h by defining $h(S) = \bigcup_{u \in S} h(u)$. For all set families $\mathcal{S}_i$, we compute new sets $h(S_i)$ for all $S_i \in \mathcal{S}_i$. Then, we decide whether the new sets satisfy the following sentence, which is another $BP[\ell]$ problem:

$$(\exists S_1) \dots (\exists S_k) (\forall u) \bigvee_{i, \ell[i]=0} \neg(u \in h(S_i)) \vee \bigvee_{i, \ell[i]=1} (u \in h(S_i)).$$

The size of the new instance is $O(nt) = O(m \cdot s(m))$, and the running time of the self-reduction is also $O(nt) = O(m \cdot s(m))$. So it is a fine-grained mapping reduction for any $k \geq 2$.

Fig. 3. The universe-shrinking process. $S_1 = \{a, b\}$ and $S_2 = \{a, b, c\}$. After the mapping h , the new sets are $h(S_1) = \{a', b', c', d'\}$ and $h(S_2) = \{a', b', c', d', e'\}$.

Figure 3 illustrates an example of the universe-shrinking self-reduction for $BP[01]$, where we look for S_1, S_2 so that $S_1 \subseteq S_2$. If they exist, then after the self-reduction, it is always true that $h(S_1) \subseteq h(S_2)$. Still, it might happen that some $S_1 \not\subseteq S_2$ but $h(S_1) \subseteq h(S_2)$. In this case, a false positive occurs. In $BP[00]$, a false negative may occur when there are two disjoint sets, but some elements in $S_1 \cap S_2$ are mapped to the same element in U' . Next we will analyze the error probability of this reduction.

Analysis. Because variables quantified by $\exists$ are interchangeable, w.l.o.g. for ℓ containing i ($i \geq 1$) zeros and $k - i$ ones, assume $BP[\ell]$ is defined by

$$(\exists S_1) \dots (\exists S_k) (\forall u) \left[\left(\bigvee_{j=1}^i (u \notin S_j) \right) \vee \left(\bigvee_{j=i+1}^k (u \in S_j) \right) \right],$$

equivalently, $(\exists S_1) \dots (\exists S_k) [(\bigcap_{j=1}^i S_j) \subseteq (\bigcup_{j=i+1}^k S_j)]$.

Let sets $A = \bigcap_{j=1}^i S_j$ and $B = \bigcup_{j=i+1}^k S_j$. Then the problem is to decide whether there exists $(S_1, \dots, S_k)$ so that $A \subseteq B$. After the self-reduction, let $A' = \bigcap_{j=1}^i h(S_j)$ and $B' = \bigcup_{j=i+1}^k h(S_j)$, and decide if there exists $(S_1, \dots, S_k)$ such that $A' \subseteq B'$.

- **False positive.** A false positive occurs when $\forall (S_1, \dots, S_k), A \not\subseteq B$, but $\exists (S_1, \dots, S_k), A' \subseteq B'$. For a fixed tuple $(S_1, \dots, S_k)$ such that $A \not\subseteq B$, an error occurs when $h(u) \subseteq B'$ for all $u \in A - B$. The size of B' is at most kdt . So the error probability $\Pr[h(u) \subseteq B'] \leq (kdt/n_u^t)^t = (ks(m) \cdot s(m)/s(m)^5)^t < s(m)^{-t}$. The size of $A - B$ is bounded by kd , so the probability $\Pr[\exists u \in A - B, h(u) \subseteq B'] \leq kd \cdot s(m)^{-t}$. There are $O(m^k)$ tuples of $(S_1, \dots, S_k)$, so the total error probability is at most $O(m^k) \cdot kd \cdot s(m)^{-t} = O(m^k \cdot s(m)/s(m)^{s(m)})$, which is exponentially small.
- **False negative.** A false negative occurs when $\exists (S_1, \dots, S_k), A \subseteq B$, but $\forall (S_1, \dots, S_k), A' \not\subseteq B'$. Fix any tuple $(S_1, \dots, S_k)$ that satisfies $A \subseteq B$ in the original instance, and consider the distribution on the corresponding $h(S_1), \dots, h(S_k)$. By definition, $B' = \bigcup_{u \in B} h(u)$, and so contains $\bigcup_{u \in A} h(u)$. So if $A' \subseteq \bigcup_{u \in A} h(u)$, we will have $A' \subseteq B'$, and there will not be a false negative. If not, then there is some $u' \in A' = \bigcap_{j=1}^i h(S_j)$, such that $u' \notin \bigcup_{u \in A} h(u)$. Then for each $j \in \{1, \dots, i\}$, in each S_j there is a $u_j \in S_j$ with $u' \in h(u_j)$, but not all u_j are identical.

(Otherwise the $u_j \in A$, so $u' \in h(u_j) \subseteq \bigcup_{u \in A} h(u)$, contradicting $u' \notin \bigcup_{u \in A} h(u)$). In particular, this means that for some j_1, j_2 , there are $u_{j_1} \in S_{j_1}, u_{j_2} \in S_{j_2}$, such that $h(u_{j_1}) \cap h(u_{j_2}) \neq \emptyset$. So the error probability is bounded by $k^2 \cdot \Pr[\exists(u_1 \in S_{j_1}, u_2 \in S_{j_2}), h(u_1) \cap h(u_2) \neq \emptyset]$. Because $|S_{j_1}|$ and $|S_{j_2}|$ are at most d , by Birthday Paradox, the probability is at most $O(k^2 d^2 t^2 / n'_u) = O(s(m)^{-1})$. This is the upper bound of the error probability for the fixed $(S_1, \dots, S_k)$ tuple. Then, the probability of the event “ $\forall(S_1, \dots, S_k), A' \not\subseteq B'$ ” is even smaller.

5.1.2 Deterministic Universe-shrinking Self-reduction of $BP[1^k]$. This section proves the remaining part of Lemma 5.2, by showing $BP[1^k]$ is either easy to solve or easy to complement. $BP[1^k]$ is the k -Set Cover problem, which decides whether there exist k sets covering the universe U . It is special in the Basic Problems: When n_u is small, the sets are easy to complement; when n_u is large, the problem is easy to solve.

- **Case 1: Large universe.** If $n_u > s(m)$, then in a solution of this problem, at least one set has size at least n_u/k . There are at most $m/(k/n_u) = O(m/s(m))$ such large sets, thus they can be listed in time $O(m/s(m))$, after pre-computation on the sizes of all sets. Our algorithm exhaustively searches all such large sets. And then, similarly to “Step 1” in Section 5.1.1, for each of the large sets, we run the baseline algorithm to find the remaining $k - 1$ sets in the k -set cover, which takes time $O(m^{k-1})$. So the overall running time is $O(m/s(m)) \cdot O(m^{k-1}) = O(m^k/s(m))$.
- **Case 2: Small universe.** If $n_u \leq s(m)$, then we do not need a universe-shrinking self-reduction, because the universe is already small enough.

5.2 Hybrid Problem

Next we reduce general $MC(\exists^k \forall)$ problems to an intermediate problem called the Hybrid Problem, which is a combination of 2^k Basic Problems. Then by reducing from the Hybrid Problem to Basic Problems, we can set up a connection between $MC(\exists^k \forall)$ and OV.

Let $k \geq 2$. The input to the Hybrid Problem is:

- (1) Set families $\mathcal{S}_1 \dots \mathcal{S}_k$ defined on universe U , where U is partitioned into 2^k disjoint sub-universes: $U = \bigcup_{\ell \in \{0,1\}^k} U_\ell$.
- (2) A binary relation R defined on pairs of sets from any two distinct set families. R is a symmetric relation ($R(S_i, S_j)$ iff $R(S_j, S_i)$).
- (3) *type* is binary string of length $\binom{k}{2}$, indexed by two integers $[i, j]$, s.t. $i, j \in \{1, \dots, k\}$ and $i < j$.

The goal of the problem is to decide if there exist $S_1 \in \mathcal{S}_1, \dots, S_k \in \mathcal{S}_k$ such that both of the following constraints are true:

- (A) For each $\ell \in \{0,1\}^k$, $(S_1, \dots, S_k)$ is a solution of $BP[\ell]$ defined on sub-universe U_ℓ .
- (B) For all pairs of indices $i, j \in \{1, \dots, k\}, i < j$, we have that $R(S_i, S_j) = \text{true}$ iff $\text{type}[i, j] = 1$.

We let n be the sum of $|S_1|, \dots, |S_k|$ and U , and let m be the number of tuples in all unary and binary relations. The Hybrid Problem is a first-order property on graphs with additional constraints. As usual, we assume all relations in the Hybrid Problem are sparse ($m \leq n^{1+o(1)}$). Figure 4 shows a solution to a Hybrid Problem instance when $k = 2$.

Intuition Behind the Hybrid Problem. In the Hybrid Problem, the set families $S_1, \dots, S_k$ encode the conditions on relations involving x_{k+1} , while the binary relation R and the *types* encode the conditions on relations not involving x_{k+1} . We mentioned in Section 4 that any first-order query containing two variables can be written in a “normal form,” which is a combination of sparse and

Fig. 4. An example of a solution to a Hybrid Problem instance, when $k = 2$. In sub-universes $U_{00}, U_{01}, U_{10}, U_{11}$, sets S_1 and S_2 are solutions of $BP[00]$ (Set Disjointness), $BP[01]$ (Set Containment), $BP[10]$ (Set Containment in the reversed direction) and $BP[11]$ (2-Set Cover), respectively. Furthermore, $type[1, 2] = 1$ specifies that the predicate R on (S_1, S_2) must be true.

co-sparse relations. The Hybrid Problem is designed for separating sparse relations from co-sparse ones, for *all* pairs of variables in formula φ .

The relation between the pair of variables (x_i, x_{k+1}) , where $1 \leq i \leq k$ can be either sparse or co-sparse. Because there are k such variables x_i , there are 2^k cases for a combination $((x_1, x_{k+1}), \dots, (x_k, x_{k+1}))$. These cases correspond to the 2^k Basic Problems. In each Basic Problem, we deal with one of the 2^k cases.

For a relation between the pair of variables (x_i, x_j) , where $1 \leq i < j \leq k$, it also can be either sparse or co-sparse. We use $type[i, j]$ to distinguish the two cases: When it is set to 1, we expect a sparse relation for (x_i, x_j) , otherwise a co-sparse relation.

5.2.1 Reduction to Basic Problems.

LEMMA 5.5. Let $s(m)$ be a non-decreasing function such that $2^{\Omega(\sqrt{\log m})} \leq s(m) < m^{1/5}$. Then, $(\text{Hybrid Problem}, m^k / (s(m))^{1/6}) \leq_{EC} (k\text{-OV}, m^k / (s(m)))$.

Given an instance of the Hybrid Problem, we can do the following modification in time $O(m)$. For each pair of indices i, j , where $1 \leq i < j \leq k$, we construct auxiliary elements depending on the value of $type[i, j]$.

- **Case 1:** If $type[i, j] = 0$, then if a pair $S_i \in \mathcal{S}_i, S_j \in \mathcal{S}_j$ occurs in a solution to the Hybrid Problem, then there should be no edge $R(S_i, S_j)$. Let ℓ be the length- k binary string, where the i th and j th bits are zeros and all other bits are ones. For each edge $R(S_i, S_j)$ on $S_i \in \mathcal{S}_i$ and $S_j \in \mathcal{S}_j$, we add an extra element $u_{S_i S_j}$ in U_ℓ and let $u_{S_i S_j} \in S_i, u_{S_i S_j} \in S_j$. Thus, $S'_i \in \mathcal{S}_i$ and $S'_j \in \mathcal{S}_j$ can both appear in the solution only when for all $u_{S_i S_j}, (u_{S_i S_j} \notin S'_i) \vee (u_{S_i S_j} \notin S'_j)$, and this holds iff $R(S'_i, S'_j) = \text{false}$.
- **Case 2:** If $type[i, j] = 1$, then in a solution to the Hybrid Problem, S_i and S_j should have an edge $R(S_i, S_j)$ between them. Let ℓ be the length- k binary string, where the j th bit is zero and all other bits are ones. For each $S_j \in \mathcal{S}_j$, we add an extra element u_{S_j} in U_ℓ and let $u_{S_j} \in S_j$. For each edge $R(S_i, S_j)$, we let $u_{S_j} \in S_i$. Thus, $S'_i \in \mathcal{S}_i$ and $S'_j \in \mathcal{S}_j$ can both appear in the solution only when for all $u_{S_j}, (u_{S_j} \notin S'_j) \vee (u_{S_j} \in S'_i)$, and it holds iff $R(S'_i, S'_j) = \text{true}$.

After the above construction, we can drop the constraint (B) of the Hybrid Problem. We will ignore the relation R and *type* in the Hybrid Problem. The problem now is to decide whether there exists tuple $(S_1, \dots, S_k)$ being a solution to all 2^k Basic Problems. Then we can use the reductions in Lemma 5.1 to reduce all these Basic Problems to $BP[0^k]$, and then combine the 2^k instances to a large $BP[0^k]$ instance. Because the reductions do not change the solutions $S_1, \dots, S_k$, there exists a solution to the large $BP[0^k]$ instance iff there exists a solution simultaneously to all the Basic Problem instances. Let U_{ℓ}' be the sub-universe of the $BP[0^k]$ instance reduced from the $BP[\ell]$ sub-problem. $(S_1, \dots, S_k)$ is a solution to all Basic Problems iff their intersection is empty on every sub-universe U_{ℓ}' , iff their intersection is empty on universe $\bigcup_{\ell \in \{0,1\}^k} U_{\ell}'$, i.e., it is a solution of a $BP[0^k]$ instance.

Multiplying the error probability in the reductions between Basic Problems by 2^k , which is a constant number, and then taking a union bound, we get similar bounds of error probability for the Hybrid Problem.

5.2.2 Turing Reduction from General $MC(\exists^k \forall)$ Problems to the Hybrid Problem. The following lemma provides the last piece of the proof that sparse k -OV is complete for $MC(\exists^k \forall)$ under fine-grained Turing reductions. The result follows by combining this lemma with Lemma 5.5.

LEMMA 5.6. *For any integer $k \geq 2$, any problem in $MC(\exists^k \forall)$ is linear-time Turing reducible to the Hybrid Problem, namely, $(MC(\exists^k \forall), T(m)) \leq_{EC} (\text{Hybrid Problem}, T(O(m)))$.*

Consider the problem MC_{φ} where $\varphi = (\exists x_1) \dots (\exists x_k)(\forall x_{k+1})\psi(x_1, \dots, x_{k+1})$. An input graph G can be preprocessed in linear time to ensure that it is a $(k+1)$ -partite graph on vertices $V = (V_1, \dots, V_{k+1})$, for example by creating $k+1$ copies of original vertex set.

W.l.o.g, we assume that for each occurrence of binary predicate $R_i(x_i, x_j)$, $i \leq j$. Let P_{k+1} be the set of unary and binary predicates in ψ that involve variable x_{k+1} , and let $P_{\overline{k+1}}$ denote the set of the other predicates not including x_{k+1} . A *partial interpretation* α for $P_{\overline{k+1}}$ is a binary string of length $|P_{\overline{k+1}}|$, that encodes the truth values assigned to all predicates in $P_{\overline{k+1}}$. For each i s.t. $1 \leq i \leq |P_{\overline{k+1}}|$, if the i th predicate in $P_{\overline{k+1}}$ is assigned to *true*, then we set the i th bit of α to one, otherwise, we set it to zero. For a tuple $(v_1, \dots, v_k)$, we say it *implies* α (denoted by $(v_1, \dots, v_k) \models \alpha$) iff when $(x_1 \leftarrow v_1, \dots, x_k \leftarrow v_k)$, the evaluations of all predicates in $P_{\overline{k+1}}$ are the same as the values specified by α .

For each $\alpha \in \{0, 1\}^{P_{\overline{k+1}}}$, we create a distinct Hybrid Problem instance H_{α} . If any of the Hybrid Problems accepts, then we accept. Let $\psi|_{\alpha}(x_1, \dots, x_{k+1})$ be ψ after replacing all occurrences of predicates in $P_{\overline{k+1}}$ by their corresponding truth values specified by α . The following steps show how to create H_{α} from α and $\psi|_{\alpha}(x_1, \dots, x_{k+1})$.

Step 1: Construction of sets. We introduce *colors*, which are partial interpretations defined on some specific subsets of the predicates concerning variable x_{k+1} . We call them “colors” because they can be considered as a kind of labels on (v_i, v_{k+1}) pairs. For each $i \in \{1, \dots, k\}$, we give all the unary predicated defined on x_i and binary predicates defined on (x_i, x_{k+1}) (including those on (x_{k+1}, x_i)) a canonical order. We use P_i to denote the set of these predicates for each i . Let a color be a partial interpretation for P_i , which is a binary string of length $|P_i|$, encoding the truth values assigned to all predicates in P_i . For each j s.t. $1 \leq j \leq |P_i|$, if the j th predicate in P_i is assigned to *true*, then we set the j th bit of the color to one, otherwise, we set it to zero. For a color $c_i \in \{0, 1\}^{|P_i|}$, we say $(v_i, v_{k+1}) \models c_i$ iff when $x_i \leftarrow v_i$ and $x_{k+1} \leftarrow v_{k+1}$, the values of all predicates in P_i are the same as the corresponding bits of c_i . We refer to the colors where all bits are zeros as the *background colors*. These colors are special because they correspond to interpretations where all predicates in

P_i are false, i.e., we cannot directly go through all pairs (v_i, v_{k+1}) , where $(v_i, v_{k+1}) \models 0^{|P_i|}$, since this is a co-sparse relation. So we need to deal with these pairs separately.

For a vertex combination $(v_1, \dots, v_{k+1})$, where $(v_i, v_{k+1}) \models c_i$ on all $1 \leq i \leq k$, the k -color-tuple $(c_1, \dots, c_k)$ forms a *color combination*, which corresponds to truth values assigned to all the predicates in P_{k+1} .

For each $v_i \in V_i$, where $1 \leq i \leq k$, we create set S_{v_i} in the set family $\mathcal{S}_i$. For each $v_{k+1} \in V_{k+1}$, and each color combination $(c_1, \dots, c_k)$ s.t. $c_i \in \{0, 1\}^{|P_i|}$ and the values of all predicates specified by $(c_1, \dots, c_k)$ make $\psi|_\alpha$ evaluate to *false* (in which case we say $(c_1, \dots, c_k)$ does not satisfy $\psi|_\alpha$), we create an element $u_{(v_{k+1}, c_1, \dots, c_k)}$ in U . We call a string $C \in \{0, 1\}^k$ an *encoding* of a color combination $(c_1, \dots, c_k)$ when on all indices $i \in \{1, \dots, k\}$, $C[i] = 1$ iff $c_i = 0^{|P_i|}$. We put each element $u_{(v_{k+1}, c_1, \dots, c_k)}$ in the sub-universe U_C iff C is an encoding of $(c_1, \dots, c_k)$.

Next we will construct the sets. For each $v_i \in V_i$, let S_{v_i} be

$$S_{v_i} = \{u_{(v_{k+1}, c_1, \dots, c_k)} \mid (c_1, \dots, c_k) \text{ does not satisfy } \psi|_\alpha, \text{ and} \\ ((c_i \neq 0^{|P_i|}, (v_i, v_{k+1}) \models c_i), \text{ or } (c_i = 0^{|P_i|}, (v_i, v_{k+1}) \not\models c_i = 0^{|P_i|}))\}.$$

To construct such sets, for each edge on (x_i, x_{k+1}) (and (x_{k+1}, x_i)), we do the following. Assume the current vertex pair is (v_i, v_{k+1}) .

- (1) First, let set S_{v_i} contain all elements $u_{(v_{k+1}, c_1, \dots, c_k)}$ in U , where c_i is a fixed color such that $(v_i, v_{k+1}) \models c_i$, and the other colors c_j can be any string in $\{0, 1\}^{|P_j|}$.
- (2) Next, let set S_{v_i} contain all elements $u_{(v_{k+1}, c_1, \dots, c_k)}$ in U , where $c_i = 0^{|P_i|}$ (here $(v_i, v_{k+1}) \not\models c_i = 0^{|P_i|}$ because there is some edge connecting v_i and v_{k+1} , meaning at least one bit in c_i is 1), and the other colors c_j can be any string in $\{0, 1\}^{|P_j|}$.

In other words, in the sub-universe labeled by 0^k , which is made up of elements $u_{(v_{k+1}, c_1, \dots, c_k)}$ such that none of the c_i equals $0^{|P_i|}$, and that $(c_1, \dots, c_k)$ does not satisfy $\psi|_\alpha$, a set S_{v_i} contains an element $u_{(v_{k+1}, c_1, \dots, c_k)}$ iff $(v_i, v_{k+1}) \models c_i$. However, in any sub-universe labeled by C , where the i th bit of C is 1, i.e., those are made up of elements $u_{(v_{k+1}, c_1, \dots, c_k)}$ such that $c_i = 0^{|P_i|}$ and that $(c_1, \dots, c_k)$ does not satisfy $\psi|_\alpha$, a set S_{v_i} contains an element $u_{(v_{k+1}, c_1, \dots, c_k)}$ iff $(v_i, v_{k+1}) \not\models c_i = 0^{|P_i|}$.

Analysis. Now we show the above construction achieves constraint (A) in the definition of the Hybrid Problem.

- Assume that $(v_1, \dots, v_k)$ does not satisfy $(\forall v_{k+1})\psi|_\alpha(x_1, \dots, x_{k+1})$, i.e., there exists some $v_{k+1} \in V_{k+1}$ such that $\psi|_\alpha(v_1, \dots, v_{k+1})$ is false. Then consider the specific color combination $(c_1, \dots, c_k)$, where on each i , $(v_i, v_{k+1}) \models c_i$. So $(c_1, \dots, c_k)$ does not satisfy $\psi|_\alpha(x_1, \dots, x_{k+1})$. Thus there exists an element $u_{(v_{k+1}, c_1, \dots, c_k)}$ in U .

If none of the colors in combination $(c_1, \dots, c_k)$ is the background color, then the encoding of $(c_1, \dots, c_k)$ is the string 0^k . Thus, the element $u_{(v_{k+1}, c_1, \dots, c_k)}$ is in sub-universe U_{0^k} . By our construction, $u_{(v_{k+1}, c_1, \dots, c_k)}$ is contained in all of $S_{v_1}, \dots, S_{v_k}$, as shown on the left side of Figure 5. This is because when we went through all the edges, at the edge between (v_i, v_{k+1}) , we put $u_{(v_{k+1}, c_1, \dots, c_k)}$ in S_{v_i} , since none of the colors is background. Thus $(\exists u \in U_{0^k})[\bigwedge_{i=1}^k (u \in S_{v_i})]$, so it is not the case that $(\forall u \in U_{0^k})[\bigvee_{i=1}^k \neg(u \in S_{v_i})]$, which means $S_{v_1}, \dots, S_{v_k}$ is not a solution of $BP[0^k]$ on sub-universe U_{0^k} .

If some of the colors c_i in the color combination $(c_1, \dots, c_k)$ equal the background color $0^{|P_i|}$, then in the encoding C of $(c_1, \dots, c_k)$, $C[i] = 1$. Thus, the element $u_{(v_{k+1}, c_1, \dots, c_k)}$ is in the sub-universe U_C . By our construction, $u_{(v_{k+1}, c_1, \dots, c_k)}$ is contained in sets S_{v_i} for all

Fig. 5. The formula is satisfied iff there exists $(S_{v_1}, S_{v_2}, \dots, S_{v_k})$ so that there does not exist such an element u in any of the sub-universes: The left figure illustrates the case where none of $c_1, \dots, c_k$ is a background color. The right is the case where only c_1 and c_3 are background colors. (The dashed lines stand for non-existing edges.)

indices i , where c_i is not the background color $0^{|P_i|}$, and is not contained in sets S_{v_j} for all indices j , where c_j is the background color $0^{|P_j|}$. The latter case is because for each index j , where c_j is the background color, there is no edge connecting the pair of vertices (v_j, v_{k+1}) . So we did not put $u_{(v_{k+1}, c_1, \dots, c_k)}$ in S_{v_j} .

(The right side of Figure 5 demonstrates the example where c_1 and c_3 are the background colors while other colors are not.)

Thus

$$(\exists u \in U_C) \left[\bigwedge_{i \in \{1, \dots, k\}, C[i]=0} (u \in S_{v_i}) \wedge \bigwedge_{i \in \{1, \dots, k\}, C[i]=1} (\neg(u \in S_{v_i})) \right],$$

so it is not the case that

$$(\forall u \in U_C) \left[\bigvee_{i \in \{1, \dots, k\}, C[i]=0} (\neg(u \in S_{v_i})) \vee \bigvee_{i \in \{1, \dots, k\}, C[i]=1} (u \in S_{v_i}) \right],$$

which means $S_{v_1}, \dots, S_{v_k}$ is not a solution of $BP[C]$ on sub-universe U_C .

- However, assume that $(v_1, \dots, v_k)$ satisfies $(\forall v_{k+1}) \psi|_{\alpha}(v_1, \dots, v_{k+1})$. We claim that for all $\ell \in \{0, 1\}^k$, $(S_{v_1}, \dots, S_{v_k})$ is a solution to Basic Problem $BP[\ell]$.

Consider the sub-universe U_C for each $C \in \{0, 1\}^k$. If $C = 0^k$, i.e., the sub-universe is U_{0^k} corresponding to $BP[0^k]$, then none of the elements $u_{(v_{k+1}, c_1, \dots, c_k)}$ in U_{0^k} contains any background color among its $c_1, \dots, c_k$. For the sake of contradiction, suppose there exists an element $u_{(v_{k+1}, c_1, \dots, c_k)}$ that is contained in all sets $S_{v_1}, \dots, S_{v_k}$. So by our construction of sets, for each $i \in \{1, \dots, k\}$, $(v_i, v_{k+1}) \models c_i$. Recall that the color combination $(c_1, \dots, c_k)$ in any element $u_{(v_{k+1}, c_1, \dots, c_k)}$ does not satisfy $\psi|_{\alpha}$. Then this means the vertex v_{k+1} does not satisfy $\psi|_{\alpha}(v_1, \dots, v_k, v_{k+1})$, which leads to a contradiction.

Thus on $(S_{v_1}, \dots, S_{v_k})$, it is not the case that $(\exists u \in U_{0^k}) [\bigwedge_{i=1}^k (u \in S_{v_i})]$, implying $(S_{v_1}, \dots, S_{v_k})$ satisfies $(\forall u \in U_{0^k}) [\bigvee_{i=1}^k \neg(u \in S_{v_i})]$. So it is a solution of the Basic Problem $BP[0^k]$ on sub-universe U_{0^k} .

If $C \neq 0^k$, for the sake of contradiction, suppose there exists an element $u_{(v_{k+1}, c_1, \dots, c_k)}$ such that among $S_{v_1}, \dots, S_{v_k}$, then it is contained in set S_{v_i} iff $C[i] = 0$. Then by our construction of sets, this means for all i such that $C[i] = 0$, $(v_i, v_{k+1}) \models c_i$; while for all i such that $C[i] \neq 0$, $(v_i, v_{k+1}) \models 0^{|P_i|} = c_i$. Combining the two statements, for all i , $(v_i, v_{k+1}) \models c_i$. Recall again that the color combination $(c_1, \dots, c_k)$ in any element $u_{(v_{k+1}, c_1, \dots, c_k)}$ does not

satisfy $\psi|_\alpha$. This implies the vertex v_{k+1} does not satisfy $\psi|_\alpha(v_1, \dots, v_{k+1})$, which leads to a contradiction.

Thus on $(S_{v_1}, \dots, S_{v_k})$, it is not the case that

$$(\exists u \in U_C) \left[\bigwedge_{i \in \{1, \dots, k\}, C[i]=0} (u \in S_{v_i}) \wedge \bigwedge_{i \in \{1, \dots, k\}, C[i]=1} (\neg(u \in S_{v_i})) \right],$$

implying $(S_{v_1}, \dots, S_{v_k})$ satisfies

$$(\forall u \in U_C) \left[\bigvee_{i \in \{1, \dots, k\}, C[i]=0} (\neg(u \in S_{v_i})) \vee \bigvee_{i \in \{1, \dots, k\}, C[i]=1} (u \in S_{v_i}) \right].$$

So it is a solution of the Basic Problem $BP[C]$ on sub-universe U_C .

In summary, there exists a tuple $(v_1, \dots, v_k)$ such that $(\forall v_{k+1})\psi|_\alpha(v_1, \dots, v_k, v_{k+1})$ holds true, iff there exist sets $(S_{v_1}, \dots, S_{v_k})$ such that for all $\ell \in \{0, 1\}^k$, $(S_{v_1}, \dots, S_{v_k})$ is a solution of Basic Problem $BP[\ell]$ on sub-universe U_ℓ . Thus our reduction satisfies constraint (A) of the Hybrid Problem.

Step 2: Construction of R and *type*. Next, we consider the predicates in P_{k+1} , which are predicates unrelated to variable x_{k+1} . We create edges for predicate R according to the current partial interpretation α .

For a pair of vertices $v_i \in V_i$ and $v_j \in V_j$, where $1 \leq i < j \leq k$, we say (v_i, v_j) agrees with α if the evaluations of all predicates on (x_i, x_j) (including (x_j, x_i)) when $x_i \leftarrow v_i, x_j \leftarrow v_j$, equals the truth values of corresponding predicates specified by α .

- **Case 1: At least one predicate on (x_i, x_j) in α is true.** (i.e., (x_i, x_j) is in a sparse relation) For all edges (v_i, v_j) (including (v_j, v_i)), where $v_i \in V_i$ and $v_j \in V_j$ and $i < j \leq k$, if (v_i, v_j) agrees with α , then we create edge $R(S_{v_i}, S_{v_j})$. Finally, we make $type[i, j] = 1$ in the Hybrid Problem H_α .
- **Case 2: All predicates on (x_i, x_j) in α are false.** (i.e., (x_i, x_j) is in a co-sparse relation) For all edges (v_i, v_j) (including (v_j, v_i)), where $v_i \in V_i$ and $v_j \in V_j$ and $i < j \leq k$, if (v_i, v_j) does not agree with α , then we create edge $R(S_{v_i}, S_{v_j})$. Finally, we make $type[i, j] = 0$ in the Hybrid Problem H_α .

Analysis. We prove that (v_i, v_j) can appear in the solution of H_α only if when it agrees with α . If (v_i, v_j) does not agree with α , then we should not let them be in any solution of H_α . This is done by the relation R and the string *type*.

Consider the two cases. If in α some predicates on (x_i, x_j) are true (i.e., set of tuples that agree with α is sparse), then in any (v_i, v_j) that agrees with α , there must be an edge in G connecting v_i and v_j . So we can add an edge (defined by relation R) on the corresponding sets S_{v_i}, S_{v_j} and require there must be such an edge in the solution (i.e., *type* being 1).

However, if all predicates on (x_i, x_j) in α are false (i.e., set of tuples agreeing with α is co-sparse), then in any (v_i, v_j) that agrees with α , there should not be any edge connecting v_i and v_j . In this case, we turn to consider the tuples (v_i, v_j) that do not agree with α (which is a sparse relation, instead of co-sparse). We create edges on the corresponding sets S_{v_i}, S_{v_j} and require there must *not* be such an edge in the solution (i.e., *type* being 0).

Therefore, a tuple $(v_1, \dots, v_k)$ implies α iff for all $i, j \in \{1, \dots, k\}, i < j$, the truth value of relation $R(S_{v_i}, S_{v_j})$ equals whether $type[i, j] = 1$. Thus our reduction satisfies constraint (B) of the Hybrid Problem.

From the analyses of the two steps, we have justified that: there exists $(v_1, \dots, v_k)$ so that $(v_1, \dots, v_k) \models \alpha$, and $\psi|_\alpha$ holds for all $v_{k+1} \in V_{k+1}$, iff there exists $(S_{v_1}, \dots, S_{v_k})$ being a solution to the Hybrid Problem H_α . Thus, if for any $\alpha \in \{0, 1\}^{P_{k+1}}$, the Hybrid Problem H_α accepts, then there exists a solution $(v_1, \dots, v_k)$ so that $\psi(v_1, \dots, v_k, v_{k+1})$ holds for all $v_{k+1} \in V_{k+1}$. Otherwise there does not exist such a solution. From the above argument, we have proved the following claim.

CLAIM 5.1. *The two propositions are equivalent:*

- (1) MC_φ has a solution $x_1 \leftarrow v_1, \dots, x_k \leftarrow v_k$ such that $(\forall v_{k+1} \in V_{k+1})\psi(v_1, \dots, v_{k+1})$ is satisfied.
- (2) There exists an $\alpha \in \{0, 1\}^{P_{k+1}}$ so that $(S_{v_1}, \dots, S_{v_k}) \models \alpha$, and $S_{v_1}, \dots, S_{v_k}$ is a solution to the Hybrid Problem H_α .

The running time of the whole reduction process is linear in the total number of edges in the graph, because the number of predicates is constant. Thus Lemma 5.6 follows.

6 DERANDOMIZATION

We derandomize the reduction in Section 5 for the $k = 2$ case, so that the whole proof of Theorems 1.2 and 1.4 is deterministic. The derandomization of the randomized universe-shrinking self-reduction uses the technique of nearly disjoint sets similar to the construction of pseudorandom generator by Nisan and Wigderson in Reference [28].

In this section, for simplicity we use $SC(x)$ (respectively, $SD(x)$) to denote Set Containment, a.k.a. the Basic Problem $BP[01]$ (respectively, Set Disjointness, a.k.a. the Basic Problem [00] or Sparse OV) on universe of size x , and use HP for the Hybrid Problem.

LEMMA 6.1. *For any $2^{\Omega(\sqrt{\log n})} \leq s < m^{1/3}$, there is a deterministic universe-shrinking self-reduction for SC such that $(SC(n), m^2/s) \leq_{EC} (SC(O(s^2 \log^2 n / \log^2 s), m^2/s^3 \frac{\log^2 n}{\log^2 s}))$.*

LEMMA 6.2. *For any $2^{\Omega(\sqrt{\log n})} \leq s < m^{1/3}$, there is a deterministic universe-shrinking self-reduction for SD such that $(SD(n), m^2/s) \leq_{EC} (SD(O(s^2 \log n / \log s), m^2/s^3 \frac{\log n}{\log s}))$.*

The following reduction from the Hybrid Problem to Set Disjointness implies the model checking for any $\exists\forall$ sentences on sparse structures can be reduced to moderate-dimension SD , and then to OV .

LEMMA 6.3. *For any $2^{\Omega(\sqrt{\log n})} \leq s < m^{1/3}$, where m is the input size to the Hybrid Problem, there is a deterministic reduction algorithm such that $(HP, m^2/s) \leq_{EC} (SD(O(s^2 \log^2 n / \log^2 s), m^2/s^7 \frac{\log^3 n}{\log^3 s}))$.*

6.1 Proof of Lemma 6.1

This section presents the derandomization of the universe-shrinking self-reduction in Sections 5.1.1 for the Basic Problem $BP[01]$ (and equivalently $BP[10]$), i.e., when the corresponding Basic Problem is the Set Containment problem.

Pick $\ell = O(\log n / \log s)$ and prime number $q = O(s \log n / \log s)$, so that $s\ell < q$ and $q^\ell > n$. By Bertrand's postulate and that PRIMES is in P, we can find such a q in time $\tilde{O}(s \log n / \log s)$.

First, we use the algorithm in Section 5.1.1 to decide if there is a solution containing a set of size at least s , which takes time $O(m^2/s)$. So next we only consider sets of size smaller than s .

We create a new universe U' of size q^2 . Let U' be $GF(q) \times GF(q)$. Let element u in universe U correspond to a unique polynomial p_u over $GF(q)$ of degree ℓ . The number of different polynomials is q^ℓ . Since $q^\ell > n$, the number of different polynomials is greater than the number of elements of U .

Let h be a hash function so that each element in U is mapped to a set $h(u) = \{\langle i, p_u(i) \rangle \mid i \in GF(q)\}$ of size q . For set $S \subseteq U$, define $h(S) = \bigcup_{u \in S} h(u)$. Finally, $S'_1 = \{h(S) \mid S \in \mathcal{S}_1\}$, and S'_2 is constructed similarly. Then we decide the $SC(q^2)$ instance that takes S'_1 and S'_2 as input.

If $S_1 \subseteq S_2$, then $h(S_1) \subseteq h(S_2)$, and the call to the $SC(q^2)$ instance returns true.

If $S_1 \not\subseteq S_2$ for all sets, we need to show that for each element $u_1 \in S_1 \setminus S_2$, $|h(u_1) \cap h(S_2)| < q$. Then because $|h(u_1)| = q$, some element in $h(u_1)$ is not in $h(S_2)$, therefore $h(S_1) \not\subseteq h(S_2)$. To show $|h(u_1) \cap h(S_2)| < q$, observe that for each element $u_2 \in S_2$, the intersection $h(u_1) \cap h(u_2)$ has size at most ℓ , the degree of polynomial $p_{u_1} - p_{u_2}$. There are at most s elements in S_2 , thus $|h(u_1) \cap h(S_2)| \leq s\ell < q$.

Thus, there exist $S_1 \subseteq S_2$ in the original instance iff there exist $h(S_1) \subseteq h(S_2)$ in the constructed instance.

The time to create the new set is $O(mq\ell)$, which is less than $O(m^2/s)$. And its size is $m' \leq mq$. Thus, if we can solve it in time $O(m'^2/\text{poly}(s))$, where $s < m^\epsilon$ for all $\epsilon > 0$, we can solve it in time $O(m^2q^2/\text{poly}(s)) = O(m^2/\text{poly}(s))$.

6.2 Proof of Lemma 6.2

First, we use the algorithm in Section 5.1.1 to decide if there is a solution containing a set of size at least s , which takes time $O(m^2/s)$. So next we only consider sets of size smaller than s .

Let $\ell = O(\log n / \log s)$, and let q be a prime $\geq s^2\ell$, thus $q = O(s^2\ell) = O(s^2 \frac{\log n}{\log s})$. So $q^\ell > n$. By Bertrand's postulate, we can find such a q in time $O(s^2 \frac{\log n}{\log s})$. We create a universe U' of size q .

Each element u of U , which is a string of length $\log n$, can be viewed as the encoding of a polynomial p_u over $GF(q)$ of degree $\frac{\log n}{\log q} \leq \frac{\log n}{\log s} = \ell$.

Let a be an element in group $GF(q)$. For each element u in U , we let hash function $h_a(u) = p_u(a)$. For set $S \subseteq U$, define $h_a(S) = \bigcup_{u \in S} \{h_a(u)\}$. The algorithm in the outermost loop enumerates all elements $a \in GF(q)$. For each a , we compute $h_a(S)$ for all sets S in the input. Then we decide if there are two disjoint sets in the new instance. The algorithm makes q queries to $SD(q)$ instances of input size m , each taking time $T(m) = m^2/s^3 \frac{\log n}{\log s} = m^2/sq$, the running time for moderate-dimension OV. The total time is $qT(m) = O(m^2/s)$.

For each pair of different elements u and v in U , the number of elements a in $GF(q)$ so that $p_u(a) = p_v(a)$ is at most their degree $\ell < \log n$. Suppose $S_1 \in \mathcal{S}_1$ and $S_2 \in \mathcal{S}_2$ are a pair of disjoint sets. $h_a(S_1)$ and $h_a(S_2)$ are disjoint if all pairs of their elements are mapped to different elements in $GF(q)$. The total number of possible collisions is at most $s^2 \log n$. Because $q > s^2 \log n$, there exists at least one element a in $GF(q)$ so that all pairs of elements in S_1 and S_2 are mapped to different elements by h_a .

If there are no disjoint sets, then for each $S_1 \in \mathcal{S}_1$ and $S_2 \in \mathcal{S}_2$, $h(S_1 \cap S_2) \subseteq h(S_1) \cap h(S_2)$, so $h(S_1)$ and $h(S_2)$ are not disjoint. Thus, for every $a \in GF(q)$, the call to the $SD(\log n)$ instance returns false.

6.3 Hybrid Problem

In this section, we combine the above two deterministic reductions to solve the Hybrid Problem, which yields a deterministic reduction for Theorem 1.2 and Theorem 1.4. Here we use a similar version of the Hybrid Problem as defined in Section 5.2 but without the relation R and the string type. More formally, we consider the Hybrid Problem defined as follows:

Problem HP

Input: $\mathcal{S}_1, \mathcal{S}_2$, each a set family of sets $S_i = A_i \cup B_i \cup C_i \cup D_i$, where A_i, B_i, C_i, D_i are subsets of disjoint universes U_A, U_B, U_C, U_D , respectively.

Output: Whether there exist $S_i \in \mathcal{S}_1$ and $S_j \in \mathcal{S}_2$ so that

- (1) $A_i \cap A_j = \emptyset$ (Set Disjointness)
- (2) $B_i \subseteq B_j$ (Set Containment)
- (3) $C_i \supseteq C_j$ (Set Containment reversed)
- (4) $D_i \cup D_j = U_D$ (2-Set Cover)

The results in Section 5.2 can be applied to this version of Hybrid Problem, so that the model checking for first-order sentences of form $\exists\exists\forall$ can be reduced to the Hybrid Problem. More precisely, $(MC(\exists\exists\forall), T(O(m))) \leq (HP, T(m))$.

PROOF OF LEMMA 6.3. First, we decide if there is a solution containing a set of size at least s , as described in the previous subsections, using time $O(m^2/s)$. So next we only consider sets of size smaller than s .

If $|U_D| \geq 2s$, then for all pairs of i, j , D_i and D_j cannot cover U_D , so we return false. Otherwise for i and all j , we create sets $U_D \setminus D_i$ and $U_D \setminus D_j$. So $D_1 \cup D_2 = U_D$ iff $(U_D \setminus D_i) \cap (U_D \setminus D_j) = \emptyset$. The resulting instance size is $O(ms)$.

Then, we use Lemma 6.1 self-reductions for Set Containment on the B 's and C 's, so the created sets B'_i, B'_j and C_i, C_j are on universes of size $O(s^2 \frac{\log^2 n}{\log^2 s})$. For each j , we create set $U_B \setminus B'_j$, so $B_i \subseteq B_j$ iff $B'_i \subseteq B'_j$ iff $B'_i \cap (U_B \setminus B'_j) = \emptyset$. Similarly for each i we create $U_C \setminus C'_i$, so $C_i \supseteq C_j$ iff $C'_i \supseteq C'_j$ iff $(U_C \setminus C'_i) \cap C'_j = \emptyset$. The resulting instance size is $O(m \cdot s^2 \frac{\log^2 n}{\log^2 s})$.

Finally, we use Lemma 6.2 self-reductions for Set Disjointness on the original A 's. So in each call to the oracle, the created sets A'_i, A'_j are on universes of size $O(s^2 \frac{\log n}{\log s})$. For each i and each j , we create sets $S'_i = A'_i \cup B'_i \cup (U_C \setminus C'_i) \cup (U_D \setminus D_i)$ and $S'_j = A'_j \cup (U_B \setminus B'_j) \cup C'_j \cup (U_D \setminus D_j)$. By the argument above, $S'_i \cap S'_j = \emptyset$ iff $A'_i \cap A'_j = \emptyset$ and $B_i \subseteq B_j$ and $C_i \supseteq C_j$ and $D_i \cup D_j = U_D$. If $A_i \cap A_j = \emptyset$, then in at least one call to the oracle $A'_i \cap A'_j = \emptyset$ and thus the call will return true as long as the conditions on B, C, D 's are satisfied. If $A_i \cap A_j \neq \emptyset$, then all calls return false.

The size of the new instance is $O(m \cdot s^2 \frac{\log^2 n}{\log^2 s})$. In the reduction, we make $s^2 \frac{\log n}{\log d}$ calls to the algorithm for Set Disjointness on small universe. Thus if $SD(O(s^2 \frac{\log^2 n}{\log^2 s}))$ has algorithms in time $O(m^2/s^7 \frac{\log^5 n}{\log^5 s})$, we get running time $s^2 \frac{\log n}{\log d} \cdot O((m \cdot s^2 \frac{\log^2 n}{\log^2 s})^2 / s^7 \frac{\log^5 n}{\log^5 s}) = O(m^2/s)$. $\square$

This gives a reduction from the general first-order model checking problems to the Hybrid Problem.

6.4 Extending to More Quantifiers

The derandomization can be extended to quantifiers $k + 1$ for integer $k \geq 2$. The reduction combines the reductions for Set Containment and Set Disjointness.

Recall from Section 5.1, a Basic Problem $BP[\ell]$, where $\ell \neq 1^k$ can be considered as deciding $(\exists S_1) \dots (\exists S_k) (\forall u) [(\bigvee_{j=1}^i (u \notin S_j)) \vee (\bigvee_{j=i+1}^k (u \in S_j))]$, or equivalently $(\exists S_1) \dots (\exists S_k)$

$[(\bigcap_{j=1}^i S_j) \subseteq (\bigcup_{j=i+1}^k S_j)]$, for some i such that $0 \leq i \leq k$. Again, we map each element in U to a set of elements in a small universe U' by some function h , and thus map each set S in U to a set $h(S)$ in U' .

Let q_1, q_2 be the q defined in Sections 6.1 and 6.2, respectively. Here q_2 is a prime number larger than $s^{k-i}\ell$. For each element u , for each element $a \in GF(q_2)$ we map it to a set of tuples $h(u) = \{\langle u_{SC}, u_{SD} \rangle \mid u_{SC} \in h^{SC}(u), u_{SD} \in h_a^{SD}(u)\}$, where h^{SC} and h_a^{SD} are the functions h and h_a defined in Sections 6.1 and 6.2, respectively, and then we make a query for the $BP[\ell]$ instance created from the mapping h . Thus we make q_2 queries in all, and accept if at least one of the queries is accepted.

If there exist sets $S_1, \dots, S_k$ such that $\bigcap_{j=1}^i S_j \subseteq \bigcup_{j=i+1}^k S_j$, by generalizing the analysis in Section 6.2, in at least one query, then the set $\bigcap_{j=1}^i h(S_j)$ does not contain any element not in $h(\bigcap_{j=1}^i S_j)$. And by generalizing the analysis in Section 6.1, in each query, the set $\bigcup_{j=i+1}^k h(S_j) = h(\bigcap_{j=1}^i S_j)$ is always contained in $h(\bigcup_{j=i+1}^k S_j)$ that is contained in $\bigcup_{j=i+1}^k h(S_j)$. So we get the following reduction: $(BP[\ell](n), m^k/s) \leq_{EC} (BP[\ell](\text{poly}(s)), m^k/\text{poly}(s))$.

7 EXTENDING ALGORITHMS AND HARDNESS RESULTS TO HYPERGRAPHS

This section gives a reduction from $MC(\exists\exists\forall)$, i.e., the model checking for $\exists\exists\forall$ formulas on hypergraphs, to the model checking for $\exists\exists\forall$ formulas on graphs, where there are only unary and binary relations. We will prove the following lemma.

LEMMA 7.1. *If $MC(\exists^k\forall)$ on graphs is solvable in time $T(m)$, then $MC(\exists^k\forall)$ on hypergraphs is solvable in $T(O(m)) + O(m^{k-1/2})$.*

For a three-quantifier formula $(\exists x)(\exists y)(\forall z) \psi(x, y, z)$, where $x \in X, y \in Y, z \in Z$, we prove that it can be decided in time $O(m^{3/2} + T(O(m)))$, where T is the running time for the model checking of three-quantifier formulas on graphs.

Let relation $N(x, y)$ be the edges of the Gaifman graph, which means $N(x, y) = \text{true}$ iff there exists some z such that there is a hyperedge $R_i(x, y, z) = \text{true}$ (the order of x, y, z can be interchanged). Note that each tuple in the relations contributes to only constantly many tuples of N . So $|N| = O(m)$, and we can construct N in linear time.

Let $\psi(x, y, z)$ be a quantifier-free formula. We define $\psi^*(x, y, z)$ be $\psi(x, y, z)$, where all occurrences of ternary predicates are replaced by *false*. Thus, it contains only unary and binary predicates. Formula $(\exists x)(\exists y)(\forall z) \psi(x, y, z)$ is equivalent to $(\exists x)(\exists y)(\forall z)[N(x, y) \wedge \psi(x, y, z)] \vee (\exists x)(\exists y)(\forall z)[\neg N(x, y) \wedge \psi^*(x, y, z)]$.

We can decide $(\exists x)(\exists y)(\forall z)[\neg N(x, y) \wedge \psi^*(x, y, z)]$ using the algorithm for graphs, because all relations are binary. To decide $(\exists x)(\exists y)(\forall z)[N(x, y) \wedge \psi(x, y, z)]$, we consider three types of x 's and y 's. Let $\text{deg}(x)$ be the degree of x in the Gaifman graph.

- **Type 1: $\text{deg}(x) \geq \sqrt{m}$.** It is similar to deciding “large sets” for Basic Problems in Section 5.1.1. In the outer loop, enumerate all such x 's. For each x , we modify the model checking problem to an instance of $MC(2)$, by treating x as a constant. The number of such x 's is at most $O(m/\sqrt{m}) = O(\sqrt{m})$, and deciding an $MC(2)$ problem runs in time $O(m)$. So the total running time is $O(\sqrt{m} \cdot m) = O(m^{3/2})$.
- **Type 2: $\text{deg}(y) \geq \sqrt{m}$.** Use the same method as above by exchanging the order of x and y . The running time is also $O(m^{3/2})$.
- **Type 3: $\text{deg}(x) < \sqrt{m}$ and $\text{deg}(y) < \sqrt{m}$.** Enumerate all pairs of such x 's and y 's. Then in the inner loop, we enumerate all their neighbors in Z . In this way, for each $z \in Z$ such that z is a neighbor of x or y , we can categorize it by the truth value of all predicates. For all other z 's, we know all the predicates are false. Thus we can decide if all $z \in Z$ satisfy ψ . Because all these x 's and y 's are adjacent, the time for enumerating pairs of x and y is $O(m)$, and the time for enumerating all their neighbors in Z is $O(\sqrt{m})$. So the total running time is $O(\sqrt{m} \cdot m) = O(m^{3/2})$.

Thus, for each pair (x, y) , where $N(x, y) = \text{true}$, we can decide the model checking for $(\forall z) \psi(x, y, z)$ in time $O(m^{3/2})$. For each pair (x, y) , where $N(x, y) = \text{false}$, $(\forall z) \psi(x, y, z)$ is true iff $(\forall z)[\neg N(x, y) \wedge \psi^*(x, y, z)]$.

Similarly, for $MC(\exists^k\forall)$ problems where $\varphi = (\exists x_1) \dots (\exists x_k)(\forall x_{k+1}) \psi(x_1, \dots, x_{k+1})$, we still consider the cases whether there exist some hyperedge between any pair of x_i, x_j , where $i, j \leq k$. We

define relation $N(x_i, x_j) = \text{true}$ iff there exists some x_k such that there is some hyperedge containing vertices x_i, x_j . We also define $\psi^*(x_1, \dots, x_{k+1})$ be $\psi(x_1, \dots, x_{k+1})$, where all occurrences of predicates with arities greater than two are replaced by *false*. So

$$\begin{aligned} \varphi &= (\exists x_1) \dots (\exists x_k) (\forall x_{k+1}) \left[\bigvee_{i,j \in \{1, \dots, k\}, i \neq j} (N(x_i, x_j) \wedge \psi(x_1, \dots, x_{k+1})) \right] \\ &\quad \vee \left[\left(\bigwedge_{i,j \in \{1, \dots, k\}, i \neq j} \neg N(x_i, x_j) \right) \wedge \psi^*(x_1, \dots, x_{k+1}) \right] \\ &= \bigvee_{i,j \in \{1, \dots, k\}, i \neq j} \left[(\exists x_1) \dots (\exists x_k) (\forall x_{k+1}) [N(x_i, x_j) \wedge \psi(x_1, \dots, x_{k+1})] \right] \\ &\quad \vee (\exists x_1) \dots (\exists x_k) (\forall x_{k+1}) \left[\left(\bigwedge_{i,j \in \{1, \dots, k\}, i \neq j} \neg N(x_i, x_j) \right) \wedge \psi^*(x_1, \dots, x_{k+1}) \right]. \end{aligned}$$

To decide $(\exists x_1) \dots (\exists x_k) (\forall x_{k+1}) [N(x_i, x_j) \wedge \psi(x_1, \dots, x_{k+1})]$, we do exhaustive search on the $k-2$ variables other than x_i and x_j (which in essence is a quantifier-eliminating downward reduction), which takes a factor of $O(m^{k-2})$ in the running time. Then we process the variables x_i, x_j, x_k in the same way as variables x, y, z in the three-quantifier problem, that takes time $O(m^{3/2})$. The total running time is $O(m^{k-1/2})$.

To decide $(\exists x_1) \dots (\exists x_k) (\forall x_{k+1}) [(\bigwedge_{i,j \in \{1, \dots, k\}, i \neq j} \neg N(x_i, x_j)) \wedge \psi^*(x_1, \dots, x_{k+1})]$, we can use the algorithm for $MC(\exists^k \forall)$ problems on graphs, because the new formula has only unary and binary relations.

8 HARDNESS OF k -OV FOR $MC(\forall \exists^{K-1} \forall)$

In this section, we present an exact complexity reduction from any $MC(\forall \exists^{k-1} \forall)$ problem to a $MC(\exists^k \forall)$ problem, establishing the hardness of k -OV for these problems. This reduction gives an extension of the reduction from Hitting Set to Orthogonal Vectors in Reference [4] to sparse structures.

LEMMA 8.1. *For $k \geq 2$ and $s(m)$ a non-decreasing function such that $2^{\Omega(\sqrt{\log m})} \leq s(m) < m^{1/5}$, let $\varphi' = (\exists x_2) \dots (\exists x_k) (\forall x_{k+1}) \psi(x_1, \dots, x_{k+1})$. There is an exact complexity reduction*

$$\left(MC_{(\forall x_1) \varphi'}, \frac{m^k}{s(\sqrt{m})} \right) \leq_{EC} \left(MC_{(\exists x_1) \varphi'}, \frac{m^k}{s(m)} \right).$$

First, we show that in problem $MC_{(\exists x_1) \varphi'}$, if graph G satisfies $(\exists x_1) \varphi'$, then we can find a satisfying value v_1 for variable x_1 by binary search. We divide the set V_1 into two halves, take each half of V_1 and query whether $(\exists x_1) \varphi'$ holds true on the graph induced by this half of V_1 together with the original sets $V_2, \dots, V_{k+1}$. If any half of V_1 works, then we can shrink the set of candidate values for x_1 by a half, and then recursively query again, until there is only one vertex v_1 left. So it takes $O(\log |V_1|)$ calls to find a v_1 in some solution. This means as long as there is a solution for $MC_{\exists x_1 \varphi'}$, we can find a satisfying v_1 efficiently, with $O(\log m)$ queries to the decision problem.

Step 1: Large degree vertices. Let $t = m^{(k-1)/k}$. We deal with vertices in $V_1 \dots V_k$ with degree greater than t . There are at most $m/t = m^{1/k}$ such vertices. After pre-computing the sizes of all the sets, these large sets can be listed in time $O(m^{1/k})$.

- **Step 1-1: Large degree vertices in V_1 .** For each vertex $v_1 \in V_1$ with degree at least t , we create a formula ψ_{v_1} on variables $x_2, \dots, x_{k+1}$ from formula ψ , by replacing occurrences of

unary predicates in ψ on x_1 by constants, and replacing occurrences of binary predicates involving x_1 by unary predicates on the other variables. Then we check if the graph induced by $V_2, \dots, V_{k+1}$ satisfies $(\exists x_2) \dots (\exists x_k)(\forall x_{k+1})\psi_{v_1}(x_2, \dots, x_{k+1})$ by running the baseline algorithm in time $O(m^{k-1})$. If the new formula is satisfied, then we mark v_1 as “good.” The total time complexity is $O(m^{1/k}) \cdot O(m^{k-1}) = O(m^{k-1+1/k})$.

- **Step 1-2: Large degree vertices in $V_2, \dots, V_k$.** Now we exhaustively search over all vertices $v_1 \in V_1$ with degree less than t in the outermost loop. For each such v_1 , we find out all vertices $v_i \in V_i$ for $2 \leq i \leq k$, with degree at least t . Again, there are at most $O(m^{1/k})$ of them.
 - **Case 1: $k > 2$.** Because variables x_2 through x_k are all quantified by $\exists$, we interchange their order so that the variable x_i becomes the second-outermost variable x_2 (and thus the current v_i becomes v_2). Next, for each v_1 and v_2 we construct a new formula $\psi_{(v_1, v_2)}$ on variables $x_3, \dots, x_{k+1}$, by regarding x_1 and x_2 as fixed values v_1 and v_2 , and then modify ψ into $\psi_{(v_1, v_2)}$ similarly to the previous step. Again, we run the baseline algorithm to check whether the graph induced by the current $V_3, \dots, V_{k+1}$ satisfies $(\exists x_3) \dots (\exists x_{k+1})\psi_{(v_1, v_2)}(x_3, \dots, x_{k+1})$, using time $O(m^{k-2})$. If the formula is satisfied, then we mark the current v_1 as “good.” The total time complexity is $O(m \cdot m^{1/k}) \cdot (m^{k-2}) = O(m^{k-1+1/k})$.
 - **Case 2: $k = 2$.** For each vertex v_2 , we mark all the v_1 ’s satisfying $\forall x_3 \psi_{(v_1, v_2, x_3)}$ as “good”. This can be done in $O(m)$ using the algorithm for the base case of the baseline algorithm, by treating the current v_2 as constant. So this process runs in time $O(m^{1/k}) \cdot O(m) = O(m^{3/2})$.

If not all vertices in V_1 with degree at least t are marked “good,” then we reject. Otherwise, go to Step 2.

Step 2: Small degree vertices. First, we exclude all the large vertices from the graph. Then for the “good” vertices found in the previous step, we also exclude them from V_1 .

Now all vertices have degree at most t . In each of $V_1, \dots, V_k$, we pack their vertices into groups where in each group the total degree of vertices is at most t . Then the total number of groups is bounded by $O(m/t)$.

For each k -tuple of groups $(G_1, \dots, G_k)$, where $G_1 \subseteq V_1, \dots, G_k \subseteq V_k$, we query the oracle deciding $MC_{(\exists x_1)\varphi'}$ whether it accepts on the subgraph induced by vertices in $G_1, \dots, G_k$. If so, then we find a vertex v_1 in V_1 so that when $x_1 \leftarrow v_1$, the current subgraph satisfies φ' . We remove this v_1 from V_1 . Then we repeat this process to find new satisfying v_1 ’s in V_1 , and remove these v_1 ’s from V_1 . When V_1 is empty, or when no new solution is found after all group combinations are exhausted, the algorithm terminates. If in the end V_1 is empty, then all $v_1 \in V_1$ are in solutions of $MC_{\exists x_1 \varphi'}$, so we accept. Otherwise, we reject.

Each query to $MC_{\exists x_1 \varphi'}$ has size $m' = O(kt) = O(t)$. Because the number of different k -tuples of groups is $O(m/t)^k = O((m/t)^k)$, the number of queries made is $O((m/t)^k + |V_1|) \cdot O(\log m) = O((m^{1/k})^k + |V_1|) \cdot O(\log m) = O(m \log m)$ times. If $MC_{\exists x_1 \varphi'}$ on input size m' is solvable in time $O(m'^k/s(m'))$, then the running time for $MC_{\exists x_1 \varphi'}$ is $O(m \log m) \cdot O(m'^k/s(m')) = O(m \log m \cdot (m^{(k-1)/k})^k/s(m^{(k-1)/k})) \leq O(m^k/s(\sqrt{m}) \cdot \log m)$. The exponent of m is less than k . Thus this is a fine-grained Turing reduction. Lemma 8.1 follows.

Note that this reduction works not only on graphs but also on structures with relations of arity greater than two.

9 BASELINE AND IMPROVED ALGORITHMS

In this section, we first present a baseline algorithm for $MC(k+1)$ that runs in time $O(n^{k-1}m)$, which also implicitly gives us a quantifier-eliminating downward reduction from any $MC(k+1)$

problem to $MC(k)$ problems for $k \geq 2$. Then, we show how to get an improved algorithm in time $m^k / 2^{\Theta(\sqrt{\log m})}$ using our reductions and the result in References [3, 16]. Finally, we present the algorithms for some specific quantifier structures in $O(m^{3/2})$, so that these problems are easy cases in first-order property problems.

9.1 Baseline Algorithm for First-order Properties

This section gives an $O(n^{k-1}m)$ time algorithm solving $MC(k+1)$ with any quantifier structure for $k \geq 1$, thus proving Lemma 9.1.

LEMMA 9.1 (QUANTIFIER-ELIMINATING DOWNWARD REDUCTION FOR $MC(k+1)$). *Let the running time of $MC(k+1)$ on graphs of n vertices and m edges be $T_k(n, m)$. We have the recurrence*

$$\begin{aligned} T_k(n, m) &\leq n \cdot T_{k-1}(n, O(m)) + O(m), \text{ for } k \geq 2. \\ T_1(n, m) &= O(m). \end{aligned}$$

By this lemma, if all problems in $MC(k)$ have algorithms in time $T(n, m)$, then any problem in $MC(k+1)$ can be solved in time $n \cdot T(n, m)$.

Base Case. We prove that when $k = 1$, $T_k(n, m) = m$. For each $v_1 \in V_1$, the algorithm computes $\#(v_1) = |\{v_2 \in V_2 \mid (v_1, v_2) \models \psi\}|$. Thus we can list the sets of v_1 s.t. $\#(v_1) > 0$ (if the inner quantifier is $\exists$), or those that satisfy $\#(v_1) = |V_2|$ (if it is $\forall$).

Let there be p_1 different unary predicates on v_1 and p_2 different unary predicates on v_2 . We partition the universes V_1 and V_2 , respectively, into 2^{p_1} and 2^{p_2} subsets, based on the truth values of all the unary predicates of the corresponding variable. The number of different pairs of subsets is a constant. Each time, we pick a pair consisting of one subset from V_1 and one subset from V_2 , and replace the unary predicates by constants. In this way, we can just consider binary predicates in the following argument.

Let $\bar{\psi}(v_1, v_2)$ be the formula where each occurrence of each negated binary relation $R_i(v_1, v_2)$ is replaced by *false*. We enumerate all tuples (v_1, v_2) connected by at least one edge. For each tuple, we evaluate $\psi(v_1, v_2)$ and $\bar{\psi}(v_1, v_2)$. Let

$$\#\psi(v_1) = \sum_{v_2 \text{ adjacent to } v_1} ([\psi(v_1, v_2) = \text{true}] - [\bar{\psi}(v_1, v_2) = \text{true}])$$

(in which the brackets are Iverson brackets). It can be computed by enumerating all tuples (v_1, v_2) connected by at least one edge. Next, because in $\bar{\psi}$ there are no occurrences of negated binary predicates, we can compute

$$\#\bar{\psi}(v_1) = \text{The number of } v_2 \text{ s.t. } \bar{\psi}(v_1, v_2) \text{ holds}$$

by first enumerating all tuples (v_1, v_2) connected by at least one edge and checking if $\bar{\psi}(v_1, v_2)$ holds, and then considering the number of non-neighboring v_2 's for each v_1 , if being a non-neighbor of v_1 also makes $\bar{\psi}(v_1, v_2)$ true. Finally, let $\#(v_1) = \#\psi(v_1) + \#\bar{\psi}(v_1)$.

This algorithm is correct, because whenever a pair (v_1, v_2) satisfies $\psi(v_1, v_2)$, there are two cases. The first is that there exists an edge between v_1 and v_2 . In this case, when we enumerate all edges, $[\psi(v_1, v_2) = \text{true}]$ equals one and $[\bar{\psi}(v_1, v_2) = \text{true}]$ equals its contribution to $\#\bar{\psi}(v_1)$. However, if there does not exist an edge between v_1 and v_2 , then the contribution of (v_1, v_2) to $\#\psi(v_1)$ is 0 and to $\#\bar{\psi}(v_1)$ is 1.

Whenever a pair (v_1, v_2) does not satisfy $\psi(v_1, v_2)$, there are also two cases. If there exists an edge between v_1 and v_2 , when we enumerate all edges, then $[\psi(v_1, v_2) = \text{true}]$ equals zero and

$[\bar{\psi}(v_1, v_2) = \text{true}]$ equals its contribution to $\#\bar{\psi}(v_1)$. However, if there does not exist an edge between v_1 and v_2 , the contributions of (v_1, v_2) to $\#\psi(v_1)$ and to $\#\bar{\psi}(v_1)$ are both 0.

Inductive Step. For $k \geq 2$, we give a quantifier-eliminating downward reduction, thus proving the recurrence relation. Assume $\varphi = (Q_1x_1) \dots (Q_{k+1}x_{k+1})\psi(x_1, \dots, x_{k+1})$. For each $v_1 \in V_1$, create new formula $\varphi_{v_1} = (Q_2x_2) \dots (Q_{k+1}x_{k+1})\psi(x_2, \dots, x_{k+1})$, and in ψ we replace each occurrence of unary predicate $R_i(x_1)$ with a constant $R_i(v_1)$, and replace each occurrence of binary predicate $R_i(x_1, x_j)$ (or $R_i(x_j, x_1)$) with unary predicate $R'_i(x_j)$ whose value equals $R_i(v_1, x_j)$ (or $R_i(x_j, v_1)$), and so on. Our algorithm enumerates all $v_1 \in V_1$, and then computes if the graph induced by $V_2, \dots, V_{k+1}$ satisfies φ_{v_1} . If x_1 is quantified by $\exists$, then we accept iff any of them accepts. Otherwise, we accept iff all of them accept. The construction of φ_{v_1} takes time $O(m)$. The created graph has $O(n)$ vertices and $O(m)$ edges. Thus the recursion follows.

This process is a quantifier-eliminating downward reduction from an $MC(k+1)$ problem to an $MC(k)$ problem. It makes $O(m)$ queries, each of size $O(m)$. Then if problems in $MC(k)$ are solvable in time $O(m^{k-1-\epsilon})$, then problems in $MC(k+1)$ are solvable in time $m \cdot O(m^{k-1-\epsilon}) = O(m^{k-\epsilon})$. This quantifier-eliminating downward reduction implies that if all $MC(k)$ have $T(n, m)$ time algorithms, then all $MC(k+1)$ problems have $n \cdot T(n, m)$ time algorithms.

From the recursion and the base case, we have the running time $O(n^{k-1}m)$ by induction. The quantifier-eliminating downward reduction from $MC(k+1)$ to $MC(3)$ in Lemma 9.1 also works for hypergraphs. We exhaustively search the first $k-2$ quantified variables, and by replacing the occurrences of these variables by constants in the formula, we can reduce the arities of relations. After the reduction, we get a hypergraph of max arity at most three.

9.2 Algorithms for Easy Cases

In this section, we show that any $(k+1)$ -quantifier problem with a quantifier sequence ending with $\exists\exists$ or $\forall\forall$ is solvable in time $O(m^{k-1/2})$. First, we use the quantifier-eliminating downward reduction to reduce the problem to a $MC(3)$ problem. Then from the next subsections, we see that these problems are solvable in $O(m^{3/2})$. Reference [35] shows improved algorithms that run in time $O(m^{1.41})$ for detecting triangles and detecting induced paths of length 2, which are special cases of $MC(\exists\exists\exists)$.

LEMMA 9.2. *Problems in $MC(\exists\exists\exists)$, $MC(\forall\forall\forall)$, $MC(\forall\exists\exists)$, and $MC(\exists\forall\forall)$ are solvable in $O(m^{3/2})$.*

In the first two subsections, we consider when the input structures are graphs. Then in the last subsection, we consider the cases when the input structures have higher arity relations.

9.2.1 Problems in $MC(\exists\exists\exists)$ and $MC(\forall\forall\forall)$. For problems in $MC(\forall\forall\forall)$, we decide its negation, which is a $MC(\exists\exists\exists)$ problem.

We define nine *Atomic Problems*, which are special $MC(3)$ problems. Let the Atomic Problem labeled by ℓ to be $MC_{(\exists x \in X)(\exists y \in Y)(\exists z \in Z)} \psi_\ell$, and referred to as $\Delta[\ell]$. It is defined on a tripartite graph on vertex sets (X, Y, Z) , whose edge sets are E_{XY}, E_{YZ}, E_{XZ} defined on $(X, Y), (Y, Z), (X, Z)$, respectively. The graph is undirected, i.e., E_{XY}, E_{YZ} , and E_{XZ} are symmetric relations. For simplicity, we define an edge predicate E so that $E(v_1, v_2)$ is true iff there is an edge in any of E_{XY}, E_{YZ}, E_{XZ} connecting (v_1, v_2) or (v_2, v_1) . Besides, we use $\deg_Y(x)$ to denote the number of x 's neighbors in Y .

The ψ_ℓ for all Atomic Problems are defined in Table 1. For problem MC_φ , where $\varphi = (\exists x \in X)(\exists y \in Y)(\exists z \in Z) \psi(x, y, z)$, we write ψ as a DNF, and split the terms. Then we decide if there is a term so that there exist x, y, z satisfying this term. On each term t , which is a conjunction of predicates and negated predicates, we work on the induced subgraph whose vertices satisfy all the positive unary predicates and falsify all the negated unary predicates defined on them in t . Then we can remove all unary predicates from the conjunction, which is now a conjunction

Table 1. Atomic Problems

$\psi_2 = E(x, y) \wedge E(x, z)$	$\psi_{2+} = E(x, y) \wedge E(x, z) \wedge E(y, z)$	$\psi_{2-} = E(x, y) \wedge E(x, z) \wedge \neg E(y, z)$
$\psi_1 = E(x, y) \wedge \neg E(x, z)$	$\psi_{1+} = E(x, y) \wedge \neg E(x, z) \wedge E(y, z)$	$\psi_{1-} = E(x, y) \wedge \neg E(x, z) \wedge \neg E(y, z)$
$\psi_0 = \neg E(x, y) \wedge \neg E(x, z)$	$\psi_{0+} = \neg E(x, y) \wedge \neg E(x, z) \wedge E(y, z)$	$\psi_{0-} = \neg E(x, y) \wedge \neg E(x, z) \wedge \neg E(y, z)$

of binary predicates or their negations. (If the conjunction is a single predicate or a single negated predicate, then we can deal with it easily, so we do not consider this case here.) If we define $E(x, y) = \bigwedge_{R \text{ is a positive binary predicate in } t} R(x, y) \wedge \bigwedge_{R \text{ is a negative binary predicate in } t} \neg R(x, y)$, and define $E(y, z)$ and $E(x, z)$ similarly, then t becomes equivalent with some Atomic Problem, or a disjunction of Atomic Problems (because variables y and z are interchangeable, the Atomic Problems and their disjunctions cover all possible cases).

In our algorithm for each problem $\Delta[\ell]$, instead of deciding the existence of satisfying x, y, z , we consider these problems as counting problems, where for each x we compute

$$\#_\ell(x) = |\{(y, z) \mid x, y, z \text{ satisfy } \psi_\ell\}|.$$

Problems $\Delta[2], \Delta[1], \Delta[0]$ can be computed straightforwardly.

- In $\Delta[2]$, $\#_2(x) = \deg_Y(x) \times \deg_Z(x)$.
- In $\Delta[1]$, $\#_1(x) = \deg_Y(x) \times (|Z| - \deg_Z(x))$.
- In $\Delta[0]$, $\#_0(x) = (|Y| - \deg_Y(x)) \times (|Z| - \deg_Z(x))$.

Next we show for labels $\ell \in \{2+, 1+, 0+, 2-, 1-, 0-\}$, problems $\Delta[\ell]$ can be computed in $O(m^{3/2})$.

Algorithm 1 solves $\Delta[2+]$, that is, for each x , counting the number of triangles that contain x . The first part of the algorithm only considers small degree y . On each iteration of the outer loop, the inner loop is run for at most $\sqrt{m}$ times. The second part only considers large degree y . Because there are at most $\sqrt{m}$ of them, the outer loop is run for at most $\sqrt{m}$ times. Therefore the running time of the algorithm is $O(m^{3/2})$.

ALGORITHM 1: $\Delta[2+]$

```

1: for all  $(x, y) \in E_{XY}$  do ▷ Small degree  $y$ 
2:   if  $\deg_Z(y) \leq \sqrt{m}$  then
3:     for all  $z$  s.t.  $(y, z) \in E_{YZ}$  do
4:       if  $(x, z) \in E_{XZ}$  then
5:          $\#_{2+}(x) \leftarrow \#_{2+}(x) + 1$ 
6:       end if
7:     end for
8:   end if
9: end for
10: for all  $y \in Y$  s.t.  $\deg_Z(y) > \sqrt{m}$  do ▷ Large degree  $y$ 
11:   for all  $(x, z) \in E_{XZ}$  do
12:     if  $(x, y) \in E_{XY}$  and  $(y, z) \in E_{YZ}$  then
13:        $\#_{2+}(x) \leftarrow \#_{2+}(x) + 1$ 
14:     end if
15:   end for
16: end for
17: if  $\#_{2+}(x) > 0$  for some  $x \in X$  then Accept
18: else Reject
19: end if

```

Algorithm 2 solves $\Delta[1+]$, which for each x counts $(x - y - z)$ paths where there is no edge between x and z . The first part is similar as $\Delta[2+]$. The second part first over-counts $(x - y - z)$ paths for all large degree y without restricting the edge between x and z , and then counts the number of over-counted cases to exclude them from the final result. In the first block, the inner loop is run for at most $\sqrt{m}$ times for each edge in E_{XY} . The second block takes time $O(m)$. The outer loop of the third block is run for at most $\sqrt{m}$ times, because there are at most $\sqrt{m}$ sets with degree at least $\sqrt{m}$. So in all, the running time is $O(m^{3/2})$.

ALGORITHM 2: $\Delta[1+]$

```

1: for all  $(x, y) \in E_{XY}$  do ▷ Small degree  $y$ 
2:   if  $\deg_Z(y) \leq \sqrt{m}$  then
3:     for all  $z$  s.t.  $(y, z) \in E_{YZ}$  do
4:       if  $(x, z) \notin E_{XZ}$  then
5:          $\#_{1+}(x) \leftarrow \#_{1+}(x) + 1$ 
6:       end if
7:     end for
8:   end if
9: end for
10: for all  $(x, y) \in E_{XY}$  do ▷ Large degree  $y$ 
11:   if  $\deg_Z(y) \geq \sqrt{m}$  then ▷ Over-counting
12:      $\#_{1+}(x) = \#_{1+}(x) + \deg_Z(y)$ 
13:   end if
14: end for
15: for all  $y \in Y$  s.t.  $\deg_Z(y) > \sqrt{m}$  do
16:   for all  $(x, z) \in E_{XZ}$  do
17:     if  $(x, y) \in E_{XY}$  and  $(y, z) \in E_{YZ}$  then
18:        $\#_{1+}(x) \leftarrow \#_{1+}(x) - 1$ 
19:       ▷ if we just over-counted the pair  $(y, z)$ , then we exclude the pair by subtracting one.
20:     end if
21:   end for
22: end for
23: if  $\#_{1+}(x) > 0$  for some  $x \in X$  then Accept
24: else Reject
25: end if

```

For $\Delta[0+]$, we first compute $\#_{2+}(x)$, which is the result of $\Delta[2+]$, and then compute $\#_{1+}(x)$ and $\#'_{1+}(x)$, which are results of $\Delta[1+]$ on vertex sets (X, Y, Z) and (X, Z, Y) , respectively. Finally, let $\#_{0+}(x) \leftarrow |E_{YZ}| - (\#_{2+}(x) + \#_{1+}(x) + \#'_{1+}(x))$.

$\#_{2-}(x), \#_{1-}(x), \#_{0-}(x)$ can be computed by respectively taking the differences of $\#_{2+}(x), \#_{1+}(x), \#_{0+}(x)$ and $\#_{2+}(x), \#_{1+}(x), \#_{0+}(x)$.

9.2.2 Problems in $MC(\forall\exists\exists)$ and $MC(\exists\forall\forall)$. For problems in $MC(\exists\forall\forall)$, we decide its negation, which is a $MC(\forall\exists\exists)$ problem.

For problem MC_φ , where $\varphi = (\forall x \in X)(\exists y \in Y)(\exists z \in Z) \psi(x, y, z)$, we use the same algorithm to compute $\#_\ell(x)$ for all $x \in X$. If the value of $\#_\ell(x)$ is greater than zero for all $x \in X$, then we accept, otherwise reject. Again, we write ψ as a DNF, and split the terms. By the same argument as the previous lemma, we transform the problem to a disjunction of Atomic Problems. If for all

$x \in X$, at least in one of the Atomic Problem, $\#_\ell(x)$ is greater than zero, then we accept; otherwise, reject.

9.2.3 Structures with Higher Arity Relations. The above algorithms can be extended to structures with relations of arity greater than two. First, we write the quantifier-free part ψ in DNF and split each term to a separate $\exists\exists\exists$ problem (or $\forall\exists\exists$, respectively). Then for each term ψ_t , we decide if there exist x_1, x_2, x_3 satisfying it. Let ψ_{t1} be the part of the conjunction containing all ternary predicates in ψ_t , and ψ_{t2} be the rest of term ψ_t . Thus $\psi_t = \psi_{t1} \wedge \psi_{t2}$.

If in ψ_t some ternary predicate occurs positively, then we can just count $\#(x_1)$ on the subgraph where ψ_{t1} is true.

If all ternary predicates in ψ_t occur negatively, then we first count $\#(x_1)$ satisfying formula ψ_{t2} , and then we count $\#'(x_1)$ on the subgraph where ψ_{t1} is true. Finally, we subtract $\#'(x_1)$ from $\#(x_1)$ for each x_1 .

If ψ_t has no ternary relations, then we just count $\#(x_1)$ using the algorithm for graphs.

10 IMPROVED ALGORITHMS

In this section, we present an algorithm solving Sparse OV in time $m^2/2^{\Theta(\sqrt{\log m})}$. It is based on the articles [3, 16], which solves dense OV for vectors of dimension d in time $n^{2-\Omega(1/\log(d/\log n))}$.

Consider the universe-shrinking self-reduction for Sparse OV (Set Disjointness) in Section 6. We show that for $s(m) = 2^{\Theta(\sqrt{\log m})}$, by the above theorem, this reduction gives an algorithm in time $m^2/2^{\Theta(\sqrt{\log m})}$. We deal with large sets and small sets separately. For sets of size at least $s(m)$, we check if each of them is disjoint with some other set. From the argument for large sets, this is in time $m^2/s(m)$. Then, for sets of size less than $s(m)$, we use the universe-shrinking self-reduction to reduce this instance to a Sparse OV instance on universe of size $s(m)^{\frac{5}{6k}}$ (in which case $k = 2$). Using the algorithm from References [3, 16], we can solve it in time $n^{2-\Theta(1/\log(s(m)^{\frac{5}{6k}}))} \leq m^{2-\Theta(1/\log(s(m)))} \leq m^2/2^{\Theta(\log m / \log s(m))} = m^2/2^{\Theta(\sqrt{\log m})}$. So the total running time is bounded by $m^2/2^{\Theta(\sqrt{\log m})}$.

By the above argument and Theorem 1.2, since all the Basic Problems are solvable in time $m^2/2^{\Theta(\sqrt{\log m})}$, so is any other problem in $MC(\exists\exists\forall)$. The reduction from $MC(\forall\exists\forall)$ to $MC(\exists\exists\forall)$ in Section 8 gives $2^{\Theta(\sqrt{\log m})}$ savings for $MC(\forall\exists\forall)$ problems. Reducing to three-quantifier case by brute-forcing over the first $k - 2$ variables we get Theorem 1.4, that states all $MC(k + 1)$ problems can be solved in $m^k/2^{\Theta(\sqrt{\log m})}$ time.

11 OPEN PROBLEMS

An obvious open problem is whether a similar kind of equivalence exists for the dense case of OV. Is it "fine-grained equivalent" to some natural complexity class?

Our results raise the possibility that many other classes have complete problems under fine-grained reducibility, and that this will be a general method for establishing the plausibility of conjectures on the fine-grained complexity of problems. There is a number of candidates for such classes. We could drop the restriction that the formula has k quantifiers in all, and look at formulas with *quantifier depth* k .⁹ We could also stratify the first-order formulas by *variable complexity*, the number of distinct variable names in a formula, rather than number of quantifiers. (Variable complexity arises naturally in database theory, because the variable complexity determines the arity of some relation in any way of expressing the query as a sequence of sub-queries.) First-order

⁹For example, $\exists(x)(\exists y(\exists z\psi_1(x, y, z) \wedge \forall z\psi_2(x, y, z)) \wedge \forall y(\exists z\psi_3(x, y, z) \vee \forall z\psi_4(x, y, z)))$ has quantifier depth 3.

logic is rather limited, so we could look at augmentations that increase its reach, such as allowing a total ordering on elements, or allowing the logic to take transitive closures of relations (e.g., to talk about the reachability relation in a sparse directed graph), or more generally, introduce monotone fixed point operations. Alternatively, rather than varying the types of formulas, we could restrict the types of structures, for example, considering structures of bounded treewidth.

It would be interesting to find more reductions between and equivalences among the problems that are proven hard under some conjecture. For example, Edit Distance, Fréchet Distance, and Longest Common Subsequence are all almost quadratically hard assuming SETH. Are there any reductions between these problems? Are they all equivalent as far as having subquadratic algorithms? All of these problems have similar dynamic programming formulations. Can we formalize a class of problems with such dynamic programming algorithms and find complete problems for this class? More generally, we would like taxonomies of the problems within P that would classify more of the problems that have conjectured hardness, or have provable hardness based on conjectures about other problems. Such a taxonomy might have to be based on the structure of the conjectured best algorithms for the problems rather than on resource limitations.

ACKNOWLEDGMENTS

First, we thank Virginia Vassilevska Williams for her inspiring ideas. We thank Marco Carmosino, Anant Dhayal, Ivan Mihajlin, and Victor Vianu for proofreading and suggestions on this article. We also thank Valentine Kabanets, Ramamohan Paturi, Ramyaa Ramyaa, and Stefan Schneider for many useful discussions. Finally, we really appreciate the suggestions from the referees about the writing and expression.
