Instructor: Una-May O'Reilly

- Leader: AnyScale Learning For All Group, MIT CSAIL
- Experience solving real world, complex problems requiring **AI/machine learning** where **evolutionary computation** is a core capability
- Applications include
 - Cybersecurity
 - Waveform data mining – medical applications
 - Behavioral data mining – MOOC
 - Circuits, network coding
 - Sparse matrix data mapping on parallel architectures
 - Finance
 - Flavor design
 - Wind energy
 - » Turbine layout
 - » Resource assessment
- Focus on innovation in genetic programming
 - coevolution
 - Improving its competence
 - scaling

Instructor: Erik Hemberg

- Research Scientist: AnyScale Learning For All Group, MIT CSAIL,
 - Experience solving complex problems requiring **AI and machine learning** with **evolutionary computation** as a core capability
 - Bronze HUMIE Award, 2017
- Applications include
 - Cybersecurity
 - Behavioral data mining – MOOC
 - Pylon design
 - Network controllers
 - Tax avoidance
- Focus on innovation and implementation in genetic programming
 - Grammatical representations
 - Coevolution
 - Estimation of Distribution and GP

About You

- EA experience?
 - ES? GA? EDA? PSO? ACO? EP?
- CS experience?
- Programming? algorithms?
- Teacher?
- Native English speakers?

Tutorial Goals

- Introduction to GP algorithm, given some knowledge of genetic algorithms or evolutionary strategies
 - provide Black box demonstration of GP symbolic regression
- Become familiar with GP design properties and recognize them
 - ponygp in python
- You could teach it in an undergrad lecture
- Use it “out of the box”
- Set groundwork for advanced topics
 - Theory, other tutorials
 - Specialized workshops (Genetic improvement etc)
 - GP Track talks at GECCO, Proceedings of EuroGP, Genetic Programming and Evolvable Machines

Agenda

1. Context: Evolutionary Computation and Evolutionary Algorithms
2. GP is the genetic evolution of executable expressions
 - Black box example of GP symbolic regression
3. Nuts and Bolts Description of Algorithm Components
4. pony_gp.py demonstration from project PonyGP
5. Resources and reference material
6. Examples

Agenda

Neo-Darwinian Evolution

- Survival and thriving in the environment
- Offspring quantity - based on survival of the fittest
- Offspring variation: genetic crossover and mutation
- Population-based adaptation over generations
- Genotype-phenotype duality
- non-deterministic

Evolutionary Computation and Evolutionary Algorithms

EA Generation Loop

Each generation

- select
- breed
- replace

```
population = random_pop_init()
generation = 0
while needToStop == false
    generation++
    solution = bestOf(population)
    phenotypes = decoder(genotypes)
    calculateFitness(phenotypes)
    parents = select(phenotypes)
    offspring = breed(parents.genotypes)
    population = replace(parents, offspring)
    recheck(needToStop)
```

Evolutionary Computation and Evolutionary Algorithms

Problem Domains where EAs are Used

- Where there is need for complex solutions
 - evolution is a process that gives rise to complexity
 - a continually evolving, adapting process, potentially with changing environment from which emerges modularity, hierarchy, complex behavior and complex system relationships
- Combinatorial optimization
 - NP-complete and/or poorly scaling solutions via LP or convex optimization
 - unyielding to approximations (SQP, GEO-P)
 - eg. TSP, graph coloring, bin-packing, flows
 - for: logistics, planning, scheduling, networks, bio gene knockouts
 - Typified by discrete variables
 - Solved by Genetic Algorithm (GA)

Evolutionary Computation and Evolutionary Algorithms

Problem Domains where EAs are Used

- Continuous Optimization
 - non-differentiable, discontinuous, multi-modal, large scale objective functions 'black box'
 - applications: engineering, mechanical, material, physics
 - Typified by continuous variables
 - Solved by Evolutionary Strategy (ES)
- Program Search
 - program as s/w system component, design, strategy, model
 - common: system identification aka symbolic regression, modeling
 - Symbolic regression is a form of supervised machine learning
 - » GP offers some unsupervised ML techniques as well
 - Clustering
 - will show a blackbox GP example soon
 - <http://flexgp.github.io/gp-learners/sr.html>
 - <http://flexgp.github.io/gp-learners/blog.html>

Evolutionary Computation and Evolutionary Algorithms

EA Individual Examples

Problem	Gene	Genome	Phenotype	Fitness Function
TSP	110	sequence of cities	tour	tour length
Function optimization	3.21	variables x of function	$f(x)$	$ min-f(x) $
graph k-coloring	permutation element	sequence for greedy coloring	coloring	# of colors
investment strategy	rule	agent rule set	trading strategy	portfolio change
Regress data	Executable sub-expression	Executable expression	model	Model error on training set (L1, L2)

Evolutionary Computation and Evolutionary Algorithms

Blackbox Example of GP Symbolic Regression

<http://flexgp.github.io/gp-learners/sr.html>
<http://flexgp.github.io/gp-learners/blog.html>

S/W by ALFA Group's FlexGP team
 Special recognition to Ignacio Araldo, PhD who prepared SR Learner tutorial and blog post

Regression

Regression

- Regress a relationship between a set of explanatory variables and a response variable
- Linear regression:
 - Assume linear model: $y=ax+b$
 - Optimize parameters (a,b) so data best fits model
- Logistic regression for classification
 - Maps linear model into sigmoid family

$$F(x) = \frac{1}{1 + e^{-(\beta_0 + \beta_1 x)}}$$

- Symbolic regression does NOT assume a model
 - Not parameter search
 - Model is intrinsic in GP solutions

FlexGP's SR Learner

- Targeted partly to be black-box for non-researchers
- sr.jar is available for download
 - Only supported for Debian linux
 - Source is on <http://flexgp.github.io>
- functionality both for performing Symbolic regression on numerical datasets and for testing the retrieved models
- Referred to as our baseline in time-aligned ALFA group publications
 - Bring Your Own Learner! A cloud-based, data-parallel commons for machine learning, Ignacio Arnaldo, Kalyan Veeramachaneni, Andrew Song, Una-May O'Reilly. IEEE Computational Intelligence Magazine, Special Issue on Computational Intelligence for Cloud Computing (Feb. 2015), Vol 10, Issue 1, pp 20-32.
 - [Multiple regression genetic programming](#), Ignacio Arnaldo, Krzysztof Krawiec, Una-May O'Reilly, GECCO '14, pp 879--886.
- Option to accelerate runs with C++ optimized execution
 - Requires gcc and g++ compilers, configuring Linux kernel parameter governing the maximum size of shared memory segments
- Option to accelerate runs with CUDA (GPU)
 - Added requirement of nvcc compiler
 - append the `-cuda` flag, make some extra directories...
- Easy parameter changing through a central file

DEMONSTRATION

- <http://flexgp.csail.mit.edu> -> LEARNERS
- <http://flexgp.github.io/gp-learners/sr.html> INSTRUCTIONS
- <http://flexgp.github.io/gp-learners/blog.html> EXAMPLE

Agenda

HOW DOES IT WORK UNDER THE HOOD?

WHAT IS THIS EXECUTABLE EXPRESSION?

Agenda

Koza's Executable Expressions

Pioneered circa 1988

- **Lisp S-Expressions**

- Composed of primitives called 'functions' and 'terminals'
- Aka operators and variables

Example:

- primitives: + - * div a b c d 4
- (*(- (+ 4 c) b) (div d a))

In a Lisp interpreter:

1. bind a b c and d
2. Evaluate expressions

% Lisp interpreter

```
(set! a 2) -> 2
(set! b 4) -> 4
(set! c 6) -> 6
(set! d 8) -> 8
(*(- (+ 4 c) b) (div d a)) -> 12
; Rule Example
(if (= a b) c d) -> 8
; Predicate:
(> c d) -> nil
```

GP Evolves Executable Expressions

A Lisp GP system

A Lisp GP system is a large set of functions which are interpreted by evaluating the entry function

- Some are definitions of primitives you write!
 - » (defun protectedDivide ...)
- Rest is software logic for evolutionary algorithms

Any GP system has a set of functions that are pre-defined (by compilation or interpretation) for use as primitives also has software logic that handles

- Population initialization, iteration, selection, breeding, replacement

GP expressions are first class objects in LISP so the GP software logic can manipulate them as data/variables as well as have the interpreter read and evaluate them

GP Evolves Executable Expressions

How to Evaluation an Expression

- interpreter beneath your code
 - Lisp example
- interpreter within your code
 - typical,
 - examples: SR.jar or ponygp.py
- compile then execute on your OS
 - older system in existence

How to Manipulate Expressions as Data

- for Crossover and Mutation we want
 - offspring can be different size and structure than parents
 - syntactic correctness
 - randomness in replication and variation
- GP solution
 - reference the abstract syntax tree
 - XO - swap subtrees between trees of parents
 - Mutation: insert, subst or delete from an AST
- A picture tells a 1000 words...

Abstract Syntax Trees

Inorder: 2+3

preorder: + 2 3

Post-order: 2 3 +

Inorder: (2-3) + (a max best)

preorder: (+ (-2 3) (max a best))

Post-order: (2 3 -) (a best max) +

- Whether parsed preorder (node, left-child, right-child) or postorder (left-child, right-child, node) or inorder (left, node, right) the expression evaluates to the same result
- (tree)GP uses an expression tree as its genotype structure

GP Evolves Executable Expressions

GP Tree Crossover

Nuts and Bolts GP Design

HVL-Mutation: substitution, deletion, insertion

Nuts and Bolts GP Design

GP Preparatory Steps

Assume we have a GP system with internal expression evaluator.

1. Decide upon functions and terminals
 - Terminals bind to decision variables in problem
 - Combinatorial expression space defines the search space
2. Set up the fitness function
 - Translation of problem goal to GP goal
 - Minimization of error between desired and evolved expression when executed
 - Maximization of a problem based score
3. Decide upon run parameters
 - Population size is most important
 - » Budget driven or resource driven
 - GP is robust to many other parameter choices
4. Determine a halt criteria and result to be returned
 - Maximum number of fitness evaluations
 - Time
 - Minimum acceptable error
 - Good enough solution (satisficing)

Nuts and Bolts GP Design

Top Level GP Algorithm

Begin

```

pop = random programs from a set of operators and operands
repeat
    execute each program in pop with each set of inputs
    measure each program's fitness
    repeat
        select 2 parents
        copy 2 offspring from parents
        crossover
        mutate
        add to new-pop
    until pop-size
pop = new-pop
until max-generation
or
adequate program found
    
```

Nuts and Bolts GP Design - Summary

Population Initialization

- Fill population with random expressions
 - Create a function set Φ and a corresponding function-count set
 - Create an terminal set (arg-count = 0), T
 - draw from Φ with replacement and recursively enumerate its argument list by additional draws from $\Phi \cup T$.
 - Recursion ends at draw of a terminal
 - requires closure and/or typing
- maximum tree height parameter
 - At max-height-1, draw from T only
- “ramped half-half” method ensures diversity
 - equal quantities of trees of each height
 - half of height's trees are full
 - » For full tree, only draw from terminals at max-height-1

Nuts and Bolts GP Design

Selection in GP

- Proceeds in same manner as evolutionary algorithm
 - Same set of methods
 - Conventionally use tournament selection
 - Also see fitness proportional selection
 - Cartesian genetic programming:
 - » One parent: generate 5 children by mutation
 - » Keep best of parents and children and repeat
 - If parent fitness = child fitness, keep child

Determining a Expression's Fitness

- One test case:
 - Execute the expression with the problem decision variables (ie terminals) bound to some test value and with side effect values initialized
 - Designate the “result” of the expression
- Measure the error between the correct output values for the inputs and the result of the expression
 - Final output may be side effect variables, or return value of expression
 - Eg. Examine expression result and expected result for regression
 - Eg. the heuristic in a compilation, run the binary with different inputs and measure how fast they ran.
 - EG, Configure a circuit from the genome, test the circuit with an input signal and measure response vs desired response
- Usually have more than one test case but cannot enumerate them all
 - Use rational design to create incrementally more difficult test cases (eg block stacking)
 - Use balanced data for regression

Nuts and Bolts GP Design

Details When Using Executable Expressions

- Closure
 - Design functions with wrappers that accept any type of argument
 - Often types will semantically clash...need to have a way of dealing with this

Practicality

- Sufficiency
 - Make sure a solution can be plausibly expressed when choosing your primitive set
 - » Functions must be wisely chosen but not too complex
 - » General primitives: arithmetic, boolean, condition, iteration, assignment
 - » Problem specific primitives
 - Can you handcode a naïve solution?
 - Balance flexibility with search space size

GP Evolves Executable Expressions

Requirements to Evolve Programs

- The search space must encompass programs of varying length and structure must compose
- Closure
- Crossover of the genotype must preserve syntactic correctness so the program can be directly executed

Nuts and Bolts GP Design

Tree Crossover Details

- Crossover point in each parent is picked at random
- Conventional practices
 - All nodes with equal probability
 - leaf nodes chosen with 0.1 probability and non-leaf with 0.9 probability
- Probability of crossover
 - Typically 0.9
- Maximum depth of child is a run parameter
 - Typically ~ 15
 - Can be size instead
- Two identical parents rarely produce offspring that are identical to them
- Tree-crossover produces great variations in offspring with respect to parents
- Crossover, in addition to preserving syntax, allows expressions to vary in length and structure (sub-expression nesting)

Nuts and Bolts GP Design

GP Tree Mutation

- Often only crossover is used
- But crossover behaves often like macro-mutation
- Mutation can be better tuned to control the size of the change
- A few different versions

Nuts and Bolts GP Design

Other Sorts of Tree Mutation

- Koza:
 - Randomly remove a sub-tree and replace it
 - Permute: mix up order of args to operator
 - Edit: + 1 3 -> 4, and(t t) -> t
 - Encapsulate: name a sub-tree, make it one node and allow re-use by others (protection from crossover)
 - » Developed into advanced GP concept known as
 - Automatic module definition
 - Automatically defined functions (ADFs)
- Make your own
 - Could even be problem dependent (what does a subtree do? Change according to its behavior)

Nuts and Bolts GP Design

Top Level GP Algorithm

Nuts and Bolts GP Design - Summary

GP Parameters

- Population size
- Number of generations
- Max-height of trees on random initialization
 - Typically 6
- Probability of crossover
 - Higher than mutation
 - 0.9
 - Rest of offspring are copied
- Probability of mutation
 - Probabilities of addition, deletion and insertion
- Population initialization method
 - Ramped-half-half
 - All full
 - All non-full
- Selection method
 - Elitism?
- Termination criteria
- Fitness function
- what is used as “solution” of expression

Nuts and Bolts GP Design

PonyGP: Simple Symbolic Regression

- Given a set of independent decision variables and corresponding values for a dependent variable
- Want: a model that predicts the dependent variable
 - Eg: linear model with numerical coefficients
 - » $Y = aX_1 + bX_2 + c(X_1X_2)$
 - Eg: non-linear model
 - » $y = a x^{1^2} + b x^{2^3}$
 - Prediction accuracy: minimum error between model prediction and actual samples
- Usually: designer provides a model and a regression (ordinary least squares, Fourier series) determines coefficients
- With genetic programming, the model (structure) and the coefficients can be learned
- Example: $y=f(x)$
- Domain of x $[-5.0, +5.0]$
- Choose the operands (terminals)
 - $X_0, X_1, 1.0, 0$
- Choose the operators (functions)
 - $+, -, *, /$ (protected)
 - protected divide: if $\text{denom}=0$, return numerator
- Fitness function: sum of mean squared error between y_i and expression's return values
- Prepare 121 points for test cases
- Random test case, out of sample ratio 70:30, random selection
- Test problem:
 - $Y=(X_0 * X_0) + (X_1 * X_1)$

GP Examples

Agenda

Context: Evolutionary Computation and Evolutionary Algorithms

1. GP is the genetic evolution of executable expressions
2. Nuts and Bolts Descriptions of Algorithm Components
3. Resources and reference material

Agenda

Reference Material

Where to identify conference and journal material

- Genetic Programming Bibliography
 - <http://www.cs.bham.ac.uk/~wbl/biblio/>
- Online Material
- ACM digital library: <http://portal.acm.org/>
 - GECCO conferences
 - GP conferences (pre GECCO),

The Block Stacking Problem Koza-92

Current State

Goal: a plan to rearrange the current state of stack and table into the goal stack

Block Stacking Example

Block Stacking Problem: Primitives

- State (updated via side-effects)
 - *currentStack*
 - *currentTable*
- The operands
 - Each block by label
- Operators returning a block based on current stack
 - top-block
 - next-needed
 - top-correct
- Block Move Operators return boolean
 - Return nil if they do nothing, t otherwise
 - Update *currentTable* and *currentStack*
 - to-stack(block)
 - to-table(block)
- Sequence Operator returns boolean
 - Do-until(action, test)
 - » Macro, iteration timeouts
 - » Returns t if test satisfied, nil if timed out
- Boolean operators
 - NOT(a), EQ(a b)

Block Stacking Example

Random Block Stacking Expressions

- eq(to-table(top-block) next-needed)
 - Moves top block to table and returns nil
- to-stack(top-block)
 - Does nothing
- eq(to-stack(next-needed) to-stack(next-needed)))
 - Moves next-needed block from table to stack 3 times
- do-until(to-stack(next-needed) (not(next-needed)))
 - completes existing stack correctly (but existing stack could be wrong)

Block Stacking Example

Block Stacking Fitness Cases

- different initial stack and table configurations (Koza - 166)
 - stack is correct but not complete
 - top of stack is incorrect and stack is incomplete
 - Stack is complete with incorrect blocks
- Each correct stack at end of expression evaluation scores 1 “hit”
- fitness is number of hits (out of 166)

Block Stacking Example

Evolved Solutions to Block Stacking

eq(do-until(to-table(top-block) (not top-block))
do-until(to-stack(next-needed) (not next-needed))

- first do-until removes all blocks from stack until it is empty and top-block returns nil
 - second do-until puts blocks on stacks correctly until stack is correct and next-needed returns nil
 - eq is irrelevant boolean test but acts as connective
 - wasteful in movements whenever stack is correct
 - Add a fitness factor for number of block movements
- do-until(eq (do-until (to-table(top-block)
(eq top-block top-correct))
(do-until (to-stack(next-needed) (not next-needed))
(not next-needed))
- Moves top block of stack to table until stack is correct
 - Moves next needed block from table to stack
 - Eq is again a connective, outer do-until is harmless, no-op

Block Stacking Example

More Examples of Genetic Programming

- Evolve priority functions that allow a compiler to heuristically choose between alternatives in hyper-block allocation
- Evolve a model that predicts, based on past market values, whether a stock's value will increase, decrease or stay the same
 - Measure-correlate-predict a wind resource
 - ICU clinical forecasting
 - » FlexGP
- Flavor design
 - Model each panelist
 - » Advanced methods for panelist clustering, bootstrapped flavor optimization
- Community Benchmarks
 - Artificial Ant
 - Boolean Multiplexor
- FlexGP
 - Cloud scale, flexibly factored and scaled GP

GP Examples

Agenda

Context: Evolutionary Computation and Evolutionary Algorithms

1. GP is the genetic evolution of executable expressions
2. Nuts and Bolts Descriptions of Algorithm Components
3. Resources and reference material
4. Examples
5. Deeper discussion (time permitting)

Agenda

How Does it Manage to Work

- Exploitation and exploration
 - Selection
 - Crossover
- Selection
 - In the valley of the blind, the one-eyed man is king
- Crossover: combining
- Koza's description
 - Identification of sub-trees as sub-solutions
 - Crossover unites sub-solutions
- For simpler problems it does work
- Current theory and empirical research have revealed more complicated dynamics

Time Permitting

Why are we still here? Issues and Challenges

- Trees use up a lot of memory
- Trees take a long time to execute
 - Change the language for expressions
 - » C, Java
 - Pre-compile the expressions, PDGP (Poli)
 - Store one big tree and mark each pop member as part of it
 - » Compute subtrees for different inputs, store and reuse
- Bloat: Solutions are full of sub-expressions that may never execute or that execute and make no difference
- Operator and operand sets are so large, population is so big, takes too long to run
- Runs “converge” to a non-changing best fitness
 - No progress in solution improvement before a good enough solution is found

Time Permitting

Runs “converge”: Evolvability

- Is an expression tree ideal for evolvability?
- Trees do not align, not mixing likes with likes as we would do in genetic algorithm
- Biologically this is called “non-homologous”
- One-point crossover
 - By Poli & Langdon
 - Theoretically a bit more tractable
 - Not commonly used
 - Still not same kind of genetic material being swapped

Time Permitting

Evolvability - modularity and reuse

- Expression tree must be big to express reuse and modularity
- Is there a better way to design the genome to allow modularity to more easily evolve?

The representation of $(x - 1)^2 + (x - 1)^3$ in a tree-based genome

Time Permitting

Evolvability: modularity and reuse

```
(1)  x=x-1
(2)  y=x*x
(3)  x=x*y
(4)  y=x+y
```

The dataflow graph of the $(x - 1)^2 + (x - 1)^3$ polynomial

Time Permitting

Register Machine Genotype

- linear genotype, varying length, direct data

Time Permitting

Register Machine Advantages

- Easier on memory and crossover handling
- Supports aligned “homologous” crossover
- Registers can act as poor-man’s modules
- The primitive level of expressions allows for
 - Potentially more easily identifiable building blocks
 - Potentially less context dependent building blocks
- The register level instructions can be further represented as machine instructions (bits) and run native on the processor
 - AIM-GP (Auto Induction of Machine Code GP)
 - Intel or PPC or PIC, java byte code,
 - Experience with RISC or CISC architectures
 - Patent number: 5946673, DISCIPLUS system

Time Permitting

Cartesian Genetic Programming

- Developer: Julian Miller
- operators and operands are nodes and data flow is described by genome
- Fixed length genome but variable length phenotype
 - Integers in blocks
 - For each block, integers to name inputs and operator
- Unexpressed genetic material can be turned on later
- No bloat observed (plus nodes are upper bounded)

Time Permitting

Dealing with Bloat

- Why does it occur?
 - Crossover is destructive
 - Effective fitness is selected for
- Effective fitness
 - Not just my fitness but the fitness of my offspring
- Approaches
 - Avoid - change genome structure
 - Remove: Koza’s edit operation
 - Pareto GP
 - Penalize: parsimony pressure
 - Fitness = $A(perf) + (1-a)(complexity)$
- “Operator equalisation for bloat free genetic programming and a survey of bloat control methods”, by [Sara Silva](#) and [Stephen Dignum](#) and [Leonardo Vanneschi](#)
 - GPEM Vol 13, #2, 2012

Examples:

- (not (not x))
- (+ x 0)
- (* x 1)
- (Move left move-right)
- If (2=1) action

No difference to fitness (defn by Banzhaf, Nordin and Keller)

Can be local or global

Time Permitting

Current GP research example:
Use of Domain Knowledge and Novelty to Improve Program Synthesis Performance

- **Human programmers solve coding problems with problem specific knowledge**
 - How can human expertise be incorporated in GP for program synthesis
- **Use GP on a Benchmark suite of 21 program synthesis problems with problem statements and input/output cases**
 - Different degrees of domain knowledge used in grammar
 - » By human
 - » By Natural Language Processing
 - Fitness function to reward program components required by problem statement
 - Novelty search: reward “novel solutions” instead of “fit”

The End
